Re: Public Hearing for the Runway Extension Project at the Ann Arbor Municipal Airport

Dear Mr. Kulhanek,

As outlined in the Notice of Public Hearing for the proposed runway extension project, comments/statements can be submitted by email and/or mail to be included in the transcript of the public hearing. As Pittsfield Charter Township's representative on the Airport Advisory Committee, I wish to submit, on Pittsfield Township's behalf, opposition to the airport runway extension project, as previously documented in the two attached Pittsfield Township Board of Trustees' Resolutions #09-23 (March 24, 2009) and #17-21 (April 12, 2017). As cited in the notice of public hearing, I request that my letter and the two attached resolutions are included in the transcript of the public hearing.

Thank you.

Respectfully,

Matthew E. Harshberger,
Director of Public Safety

PITTSFIELD CHARTER TOWNSHIP
WASHTENAW COUNTY, MICHIGAN
RES #09-23
RESOLUTION OPPOSING PROPOSED EXPANSION OF THE ANN ARBOR MUNICIPAL AIRPORT RUNWAY

MARCH 24, 2009

Minutes of a Regular Meeting of the Township Board of Pittsfield Charter Township, Washtenaw County, Michigan, held at the Township Administration Building located at 6201 W. Michigan Avenue, in said Township, on the 24th day of March, at 6:30 p.m.

Members Present: Grewal, Israel, Scribner, Ferguson, Hunt, Krone, Yi.
Members Absent: None.

The following preamble and resolution were offered by Member Scribner and supported by Member Ferguson.

WHEREAS, the Ann Arbor airport is under the jurisdiction of the City of Ann Arbor and operated by an independent Authority and the land is located within Pittsfield Charter Township immediately adjacent to a residential area; and

WHEREAS, the existing width and length has not posed any substantial safety concerns in the past with only five incidents of landing mishaps out of a total of 600,000 landings in the past eight years; and

WHEREAS, the proposed changes and expansion would shift the runway dangerously close to a busy township roadway (Lohr Road) and closer to dense residential subdivisions; and

WHEREAS, such a runway expansion will significantly increase air traffic volumes and noise pollution experienced by residential subdivisions in the vicinity of the Ann Arbor airport, thereby resulting in a decline of residential home property values; and

WHEREAS, the City of Ann Arbor has not fully demonstrated the economic and safety justifications for undertaking the proposed runway expansion; and

WHEREAS, the City of Ann Arbor appears to have not taken into consideration the negative safety implications such a runway expansion may impose on the surrounding residential subdivisions by expanding a runway closer to residential subdivisions

NOW THEREFORE BE IT RESOLVED, the Pittsfield Charter Township Board of Trustees urges the City of Ann Arbor to reconsider the merits of expanding the Ann Arbor Airport runway in light of the negative implications such an expansion would impose on the residents of Pittsfield Charter Township.

AYES:	Grewal, Israel, Scribner, Ferguson, Hunt, Krone, Yi.
NAYS:	None.
ABSENT:	None.
ABSTAIN:	None.

RESOLUTION DECLARED ADOPTED.

Alan Israel

Alan Israel, Clerk
Pittsfield Charter Township

PITTSFIELD CHARTER TOWNSHIP
WASHTENAW COUNTY, MICHIGAN
RES #17-21
RESOLUTION OPPOSING PROPOSED EXTENSION OF THE ANN ARBOR MUNICIPAL AIRPORT RUNWAY

April 12, 2017

At a Regular Meeting of the Township Board of Pittsfield Charter Township, Washtenaw County, Michigan, held at the Township Administration Building located at 6201 W. Michigan Avenue, in said Township, on the 12[th] day of April, 2017 at 6:30 p.m.

Present: Grewal, Anzaldi, Scribner, Edwards-Brown, Jaffer, Krone, Ralph.
Absent: None.

The following preamble and resolution were offered by Treasurer Scribner, and supported by Trustee Ralph.

WHEREAS, the Pittsfield Township Board of Trustees first adopted a resolution opposing the proposed runway expansion/extension on March 24, 2009 that expressed concerns centered around safety and decline in property values (Resolution #09-23); and

WHEREAS, in the eight (8) years since the adoption of Resolution No. 09-23, Pittsfield Township has not only steadfastly opposed the runway extension, it has fostered a strong partnership with the Committee for Preserving Community Quality, established by Pittsfield Township residents also opposed to the runway extension at the Ann Arbor Municipal Airport; and

WHEREAS, it is readily apparent that any runway extension will increase the viability of passenger and commercial jet aircraft usage at the Ann Arbor Municipal Airport thereby not only significantly compromising public safety and property values but also increasing air pollution and potential groundwater contaminants and, furthermore, this extension will detract from the considerable monetary and community investments made in the last few years by Washtenaw County, Ann Arbor SPARK and others toward the revitalization of the east side of Washtenaw County, specifically in and around the Willow Run airport; and

WHEREAS, Pittsfield Township and the Committee for Preserving Community Quality have extensively and specifically documented (officially by way of responses to the Environment Assessments and otherwise) our reasons for opposing the runway extension, which include, but are not limited to: (1) planes landing to the East on an expanded runway just 93 feet over Pittsfield homes, posing danger to residents; (2) Ann Arbor has not justified a proper Purpose and Need for the expansion, and the minimum required operations for expansion have not been met; (3) the Environmental Assessments do not acknowledge the potential dangers resulting from the presence of large numbers of Canada geese surrounding the airport through much of the year; (4) the expansion would attract larger and heavier aircraft closer to the population center, likely in violation of the Pittsfield Noise Ordinance; (5) any pilot could land any type of plane – no matter how large -- at any time because it is a municipal airport funded with federal tax dollars; (6) and that these risks could pose dangers to the safety of water in wells located on airport property, for which the airport property was originally acquired almost a century ago for water rights, wells which provide drinking water to Ann Arbor and an aquifer that flows throughout Pittsfield Township; and

WHEREAS, the City of Ann Arbor has, despite the very significant safety and environmental concerns noted above, included the proposed runway extension in their capital improvement plan; and

WHEREAS, the second Environmental Assessment (conducted because of egregious flaws of the first one), that includes over 200 public comments with only seven (7) in support of the proposed extension, is currently in the review process by the Federal Aviation Administration; and

WHEREAS, the Pittsfield Township Board of Trustees wants to not only reiterate our continued and steadfast opposition to the runway expansion/extension, we want to expressly and officially request a test by the United States Environmental Protection Agency) (EPA) of the aquifer located at the Ann Arbor Municipal Airport, since the 2016 Ann Arbor Municipal Airport Draft Environmental does not report any water testing data; and

WHEREAS, the City of Ann Arbor has worked with the EPA to retroactively address water quality issues as related to the Dixoane Plume, Pittsfield Township would like to request the EPA to proactively address negative impacts to water quality (that is consumed by City of Ann Arbor and Pittsfield Township residents) that may result from the proposed extension of the runway at the Airport;

NOW THEREFORE BE IT RESOLVED, the Pittsfield Charter Township requests Congresswoman Debbie Dingell, State Senator Rebekah Warren, State Representative Adam Zemke and County Commissioner Felicia Brabec to advocate on this matter with the EPA and request that EPA conduct a test of the aquifer located at the Ann Arbor Municipal Airport; and

BE IT FURTHER RESOLVED that copies of this resolution shall be provided to Congresswoman Debbie Dingell, State Senator Rebekah Warren, State Representative Adam Zemke and County Commissioner Felicia Brabec, and City of Ann Arbor councilmembers.

ROLL CALL VOTE:

AYES: Grewal, Anzaldi, Scribner, Edwards-Brown, Jaffer, Krone, Ralph.
NAYS: None.
ABSENT: None.
ABSTAIN: None.

RESOLUTION DECLARED ADOPTED.

Mandy Grewal, Supervisor
Pittsfield Charter Township

DATED: April 13, 2017

CERTIFICATE

I, Michelle L. Anzaldi hereby certify that the foregoing is a true and complete copy of a resolution adopted by the Township Board of Pittsfield Charter Township, County of Washtenaw, State of Michigan, at a Regular Meeting held on April 12, 2017, and that said meeting was conducted and public notice of said meeting was given pursuant to and in full compliance with the Open Meetings Act, being Act 267, Public Acts of Michigan, 1976, and that the minutes of said meeting were kept and will be or have been made available as required by said Act.

Re: Ann Arbor Airport – Runway 6/24 Draft Environmental Assessment, Ann Arbor, Washtenaw County, Michigan

Dear Messrs. Doyle and Houtteman:

The U.S. Environmental Protection Agency has reviewed the November 2022 Draft Environmental Assessment (Draft EA) for proposed upgrades at Ann Arbor Airport (Airport). Our comments in this letter are provided in accordance with our responsibilities under the National Environmental Policy Act (NEPA), the Council on Environmental Quality's NEPA Implementing Regulations (40 CFR 1500-1508), and Section 309 of the Clean Air Act.

The Draft EA indicates the proposed project includes:

- extending Runway 6/24 by 720 feet at the approach end of Runway 6 to provide 4,225 feet of runway length,
- shifting Runway 6/24 to the southwest by adding an additional 150 feet on the Runway 6 end and removing 150 feet on the Runway 24 end,
- extending Taxiway A parallel to the southwest to match the Runway 6/24 length,
- relocating Taxiway A1 150 feet to the southwest and reconstructing to correct a taxiway intersection with Runway 6/24,
- constructing new connector taxiway at the end of Runway 6, and
- relocating Taxiway D 150 feet to the southwest and reconstructing.

The Draft EA analyzes the impacts from two alternatives: no build and the proposed build alternative. After reviewing the Draft EA and appendices, EPA has the following comments pertaining to water and air impacts, construction debris, wildlife hazards, and project commitments.

Water Impacts

The Draft EA indicates surface water runoff is directed to the Airport's existing drainage system. However, the Draft EA is silent as to whether de-icing chemicals are used at the Airport. If planes are de-iced, EPA recommends considering biofiltration to remove chemicals before they reach the drainage system and local streams. See Water Resources/Water Quality response #5

Air Impacts

EPA acknowledges the recommendations to reduce temporary air quality impacts for both workers and the surrounding area found in Section 3.4 of the Draft EA. Additional applicable measures to reduce impacts outlined in the enclosed "*Construction Emission Control Checklist*" should become commitments in the Finding of No Significant Impact (FONSI).

See Air Quality response #5

Wildlife Hazards

The Draft EA indicates white-tailed deer and birds have been struck at the Airport. Appendix K, Wildlife Site Visit, recommends building a deer fence and installing grates in the two culverts leading into the airfield to prevent access. However, the Draft EA is silent as to whether fencing and grates will be installed. EPA strongly recommends the recommendations found in Appendix K become project commitments if a FONSI is signed for the prosed project.

Additionally, EPA recommends using Wildlife Control K-9s to proactively manage wildlife and increase aviation safety. Cherry Capitol Airport successfully made use of this program in the past. See Wildlife response #1, Safety/Health responses #1 and #8

Construction Debris

Removing pavement presents opportunities for reuse and recycling of materials, which benefits the environment and preserves valuable landfill capacity. The Draft EA is silent regarding the potential for reuse and/or recycling of pavement materials. EPA recommends applicable practices from EPA's Sustainable Management of Construction and Demolition Materials webpage[1] and EPA's Large-Scale Residential Demolition webpage[2] are identified and incorporated into contract language for bid packages. Additionally, the potential for the use of recycled materials in pavement applications and replacement of carbon-intensive Portland Cement in concrete should be considered. See General response #30

Commitments to Reduce Impacts

The Draft EA includes best management practices (BMPs) that should be considered to prevent and minimize impacts (Table 3-7). However, the Draft EA does not indicate whether these best management practices will be included in project design/implementation if a FONSI is signed. EPA strongly recommends BMPs included in the Draft EA, as well as applicable measures found

[1] https://www.epa.gov/smm/sustainable-management-construction-and-demolition-materials
[2] https://www.epa.gov/large-scale-residential-demolition

in EPA's "*Construction Emission Control Checklist,*" become project commitments as part of a FONSI.

See General response #31

The National Archives and Records Administration and the Office of Management and Budget have mandated that Federal agencies transition business processes and recordkeeping practices to fully electronic environments. Please help achieve this goal by eliminating paper mail as much as possible and send a copy of the Finding of No Significant Impact for this project electronically. If you have any questions, please contact Kathy Kowal, the lead reviewer for this project, at kowal.kathleen@epa.gov. Ms. Kowal is also available at 312-353-5206.

Sincerely,

Kathy Triantafillou
Acting Deputy Director
Tribal and Multi-media Programs Office
Office of the Regional Administrator

Enclosure: Construction Emission Control Checklist

cc via email:
Matt Kulhanek, Airport Manager, Ann Arbor Municipal Airport
William Ballard, Mead & Hunt, Inc.
Melissa Letosky, Michigan Department of Environment, Great Lakes, and Energy

U.S. Environmental Protection Agency
Construction Emission Control Checklist

Diesel emissions and fugitive dust from project construction may pose environmental and human health risks and should be minimized. In 2002, EPA classified diesel emissions as a likely human carcinogen, and in 2012 the International Agency for Research on Cancer concluded that diesel exhaust is carcinogenic to humans. Acute exposures can lead to other health problems, such as eye and nose irritation, headaches, nausea, asthma, and other respiratory system issues. Longer term exposure may worsen heart and lung disease.[3] We recommend the following applicable protective measures become commitments for Ann Arbor Airport improvements.

Mobile and Stationary Source Diesel Controls

Purchase or solicit bids that require the use of vehicles that are equipped with zero-emission technologies or the most advanced emission control systems available. Commit to the best available emissions control technologies for project equipment in order to meet the following standards.

- On-Highway Vehicles: On-highway vehicles should meet, or exceed, the EPA exhaust emissions standards for model year 2010 and newer heavy-duty, on-highway compression-ignition engines (e.g., long-haul trucks, refuse haulers, shuttle buses, etc.).[4]
- Non-road Vehicles and Equipment: Non-road vehicles and equipment should meet, or exceed, the EPA Tier 4 exhaust emissions standards for heavy-duty, non-road compression-ignition engines (e.g., construction equipment, non-road trucks, etc.).[5]
- Low Emission Equipment Exemptions: The equipment specifications outlined above should be met unless: 1) a piece of specialized equipment is not available for purchase or lease within the United States; or 2) the relevant project contractor has been awarded funds to retrofit existing equipment, or purchase/lease new equipment, but the funds are not yet available.

Consider requiring the following best practices through the construction contracting or oversight process:

- Establish and enforce a clear anti-idling policy for the construction site.
- Use onsite renewable electricity generation and/or grid-based electricity rather than diesel-powered generators or other equipment.
- Use electric starting aids such as block heaters with older vehicles to warm the engine.
- Regularly maintain diesel engines to keep exhaust emissions low. Follow the manufacturer's recommended maintenance schedule and procedures. Smoke color can signal the need for maintenance (e.g., blue/black smoke indicates that an engine requires servicing or tuning).
- Where possible, retrofit older-tier or Tier 0 nonroad engines with an exhaust filtration device before it enters the construction site to capture diesel particulate matter.
- Replace the engines of older vehicles and/or equipment with diesel- or alternatively-fueled engines certified to meet newer, more stringent emissions standards (e.g., plug-in hybrid-electric vehicles, battery-electric vehicles, fuel cell electric vehicles, advanced technology locomotives, etc.), or with zero emissions electric systems. Retire older vehicles, given the significant contribution of vehicle emissions to the poor air quality conditions. Implement

[3] Carcinogenicity of diesel-engine and gasoline-engine exhausts and some nitroarenes. *The Lancet.* June 15, 2012
[4] http://www.epa.gov/otaq/standards/heavy-duty/hdci-exhaust.htm
5 https://www.epa.gov/emission-standards-reference-guide/epa-emission-standards-nonroad-engines-and-vehicles

programs to encourage the voluntary removal from use and the marketplace of pre-2010 model year on-highway vehicles (e.g., scrappage rebates) and replace them with newer vehicles that meet or exceed the latest EPA exhaust emissions standards, or with zero emissions electric vehicles and/or equipment.

Fugitive Dust Source Controls

- Stabilize open storage piles and disturbed areas by covering and/or applying water or chemical/organic dust palliative, where appropriate. This applies to both inactive and active sites, during workdays, weekends, holidays, and windy conditions.
- Install wind fencing and phase grading operations where appropriate and operate water trucks for stabilization of surfaces under windy conditions.
- When hauling material and operating non-earthmoving equipment, prevent spillage and limit speeds to 15 miles per hour (mph). Limit speed of earth-moving equipment to 10 mph.

Occupational Health

- Reduce exposure through work practices and training, such as maintaining filtration devices and training diesel-equipment operators to perform routine inspections.
- Position the exhaust pipe so that diesel fumes are directed away from the operator and nearby workers, reducing the fume concentration to which personnel are exposed.
- Use enclosed, climate-controlled cabs pressurized and equipped with high-efficiency particulate air (HEPA) filters to reduce the operators' exposure to diesel fumes. Pressurization ensures that air moves from inside to outside. HEPA filters ensure that any incoming air is filtered first.
- Use respirators, which are only an interim measure to control exposure to diesel emissions. In most cases, an N95 respirator is adequate. Workers must be trained and fit-tested before they wear respirators. Depending on the type of work being conducted, and if oil is present, concentrations of particulates present will determine the efficiency and type of mask and respirator. Personnel familiar with the selection, care, and use of respirators must perform the fit testing. Respirators must bear a NIOSH approval number.

Subject: FW: EXE00129/Ballard/Review of Ann Arbor Environmental Assessment draft - Proposed Extension of Runway 6-24

I have reached out to Sara Thomas with Fisheries, and she has already sent her comments to Taunia, but I have also attached them in case you need them.

After my review of this document, I feel there would be little impact on wildlife as current habitat is already mowed and severely degraded by invasives species. My only concern would have been nesting season with Henslow's Sparrow, but they addressed this in the document with the agreement in place with Audubon and the mowing restrictions.

See Wildlife response #1

Hi Taunia,

Any impacts to fisheries resources from this expansion will be negligible. Fisheries Division has no objections to the preferred alternative state in the Environmental Assessment.

See Water Resources/Water Quality response #8

VIA EMAIL

William Ballard, AICP
Mead and Hunt, Inc.
2605 Port Lansing Road
Lansing, Michigan 48909

Dear William Ballard:

SUBJECT: Early Coordination Review of Proposed Extension of Runway 6/24;
Ann Arbor Municipal Airport, Ann Arbor, Michigan
Washtenaw County, T03S R06E Sections 17, and 18; Pittsfield Township
Michigan Department of Environment, Great Lakes, and Energy (EGLE)
Water Resources Division (WRD)

Thank you for your December 15, 2022, early coordination letter regarding the development of a Draft Environmental Assessment (EA) for the extension of Runway 6/24 at the Ann Arbor Municipal Airport, Ann Arbor, Michigan.

The scoping information provided indicates that the Federal Aviation Administration (FAA), and Michigan Department of Transportation (MDOT) Aeronautics have authorized the airport to explore alternatives designed to meet current and future fleet mix needs. Specifically, the preferred alternative, Alternative 2, includes the proposed improvements:

- Extend Runway 6/24 720 feet at the approach end of Runway 6 to provide 4,225 feet of runway length;

- Shift Runway 6/24 to the southwest by adding an additional 150 feet on the Runway 6 end and removing 150 feet on the Runway 24 end;

- Taxiway A - Extend parallel to the southwest to match the Runway 6/24 length;

- Taxiway A1 – Relocate 150 feet to the southwest and reconstruct to comply with FAA Advisory Circular (AC) 150/5300-13B, Section 4.8.1 to correct the taxiway intersection with Runway 6/24 to connect at a right angle;

- Taxiway A4 – Construct new connector taxiway at the Runway 6 end;

• Taxiway D – Relocate 150 feet to the southwest and reconstruct to comply FAA AC 150/5300-13B, Section 4.3.5 which prohibits direct access from an apron to a runway without requiring a turn by aircraft prior to reaching the runway;

The WRD can offer the following comments regarding statutes administered by our program:

a) Wood Outlet Drain is present along the western, and southern boundaries of Ann Arbor Municipal Airport. Proposed Runway 6/24 extension will encroach upon this drain, especially the enclosed portion of the drain at the southwestern limits of the project. Any construction below the ordinary high water mark of this drain, modification of the existing drain enclosure, additional enclosure of the drain, or relocation of the drain will require a permit under Part 301, Inland Lakes and Streams, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA). Stream mitigation may be required for unavoidable stream impacts as a result of this project. See Water Resources/Water Quality response #8

b) There may be a floodplain present associated with Wood Outlet Drain that is regulated under state law. Any filling, occupation, or grading within the 100-year floodplain of Wood Outlet Drain, if it has a drainage area of two square miles or more, will require a permit under the State's Floodplain Regulatory Authority, found in Part 31, Water Resources Protection, of the NREPA. See Water Resources/Water Quality response #8

c) Available wetland inventories indicate the presence of wetland throughout the southern portion of the Ann Arbor Municipal Airport property, including within portions of the property actively maintained by mowing, and at the southwest end of the proposed Runway 6/24 extension. Any tree or shrub removal, excavation, filling, grading, or construction that occurs in these wetlands will require a permit under Part 303, Wetlands Protection, of the NREPA. All wetland areas within the project limits should be delineated by a professional wetland consultant, and then submitted to Transportation Review Unit (TRU) for verification. Our recommendation is to submit a Voluntary Preliminary Review (VPR) request form in MiEnviro for verification of wetland delineations, and discussion of permitting requirements and limitations. Mitigation may be required for any unavoidable wetland impacts, as a result of this project. It should be noted that wetland delineations completed by your wetland consultant in 2018, and 2019 have not been verified by WRD. Thus, we recommend requesting a VPR so that those wetland delineations can be reviewed, and verified. See Water Resources/Water Quality response #2

d) A review of our database indicates potential State and/or Federal Threatened and Endangered species Indiana Bat (*Myotis sodalis),* Northern Longeared Bat (*Myotis septentrionalis),* and state listed Henslow's Sparrow (*Ammodramus hanslowii*) within the project area. Henslow's Sparrow has known occurrences within the Ann Arbor Municipal Airport property. It will be required that this project be screened using the U.S. Fish and Wildlife Service's on-line Threatened and Endangered species screening tool, iPAC. The clearance letter generated from this screening process for Indiana Bat and Northern Longeared Bat will need to be provided with your permit application submitted for regulated activities under Parts 31, 301, and 303. Work limitations during the breeding and nesting season of Henslow's Sparrow from spring to mid-summer will be required in conditions included with any permit issued for Part 31, 301, and 303 regulated activities.

See Wildlife response #1

Thank you for the opportunity to comment on this EA. If you have any questions regarding this letter, please contact me at 517-256-1469; SkubinnaJ@Michigan.gov; or EGLE, WRD, Transportation Review Unit, P.O. Box 30458, Lansing, Michigan 48909.

Sincerely,

John Skubinna
Environmental Quality Analyst
Water Resources Division

cc: Steve Houtteman, MDOT

Note:
The 2022 Draft EA was completed as a new effort independent of previous Environmental Assessments to provide a current review of the NEPA-defined environmental categories concerning the proposed extension of Runway 6/24.

Although the 2022 Draft EA is referred to as the "second revised Draft Environmental Assessment" (SRDEA)" throughout this letter, that is incorrect. There is presently only one draft version of the document from this process that may be revised pending comments received from the public outreach process.

Re: Comments of Pittsfield Charter Township and the Committee for Preserving Community Quality on Michigan Department of Transportations' Second Revised Draft Environmental Assessment for the Extension of the Runway at Ann Arbor Municipal Airport

Dear Mr. Kulhanek and Mr. Houtteman,

These comments are submitted on behalf of The Charter Township of Pittsfield (Pittsfield) and the Committee for Preserving Community Quality (CPCQ) on the second revised Draft Environmental Assessment (SRDEA) dated November 2022, and released to the public on November 13, 2022. The SRDEA was drafted by Mead and Hunt and prepared for the Federal Aviation Administration and Michigan Department of Transportation, Office of Aeronautics (MDOT). These comments are timely because on December 15, 2022, an Agency Coordination letter was sent indicating that all who received the letter could submit comments until January 18, 2023.

Table of Contents

I. Introduction

"The care of human life and happiness and not their destruction is the first and only legitimate object of good government."
- ***Thomas Jefferson, Letter to the Republican Citizens of Washington County Maryland (March 31, 1809)***

"The Federal Aviation Act requires a delicate balance between safety and efficiency, and the protection of persons on the ground."
- ***City of Burbank v. Lockheed Terminal, 411 U.S. 624 (1973*)**

This is the third draft Environmental Assessment that Ann Arbor Municipal Airport (ARB) has put forth for the same the proposed project. The first, dated February 2010, was prepared by JJR, Inc. To which Pittsfield Township submitted public comments on April 19, 2010. Exhibit 1. The second, dated December 2016, was prepared by SmithGroupJJR, to which Pittsfield Township submitted public comments on February 10, 2017. Exhibit 2. None of the previous draft environmental assessments became final. Neither MDOT nor ARB has offered any response to the comments submitted. Appendix N of the SRDEA purports to be responses to the comments submitted to prior draft environmental assessments.

In addition, on January 28, 2013, Pittsfield Township submitted a Petition to Deny Approval and Funding for the Major Runway Extension Project at Ann Arbor Municipal Airport (ARB) Located in Pittsfield Charter Township, Michigan to the Secretary of Transportation. Exhibit 3. Although the FAA responded to the portions that concerned it on December 31, 2013, Pittsfield is awaiting a response from the Department of Transportation to whom the Petition was addressed. To the extent that the Petition was premature, Pittsfield will renew its Petition with the Department of Transportation.

Finally, Pittsfield responded on May 30, 2019, to Mead & Hunt's April 15, 2019, requesting comments on specific issues. Exhibit 4. That letter is not included in the Appendix N of the SRDEA that purports to letters received in response to ARB's "Early Agency Coordination." Nor does the SRDEA address any of the questions and comments raised by Pittsfield's letter. A revised SRDEA should be issued that includes Pittsfield's letter and addresses the comments, concerns, and questions raised in that letter. See General Response #32

Pittsfield incorporates by reference its previous comments, its Petition and its May 30, 2019, letter to Mead and Hunt. Pittsfield also incorporates by reference all other public comments that oppose the construction of the unneeded runway extension. As indicated in the two Resolutions that Pittsfield has passed opposing the extension, Pittsfield reiterates, once again, its continued and steadfast opposition to the runway extension and expansion of the airport.

II. The SRDEA Does Not Meet the Requirements of the State Block Grant Program.

The SRDEA mentions that the Project is being completed under Michigan's State Block Grant Program ("SBGP"), where FAA provides funds to the relevant state agency and that agency then "administers" the program. SRDEA, p. 1-5 – 1-6. There is, however, some question as to whether Michigan Department of Transportation has retained its ability to administer the SBGP. The most recent Memorandum of Agreement, MDOT Contract No. 2010-0204, is dated March 25, 2010 ("2010 Agreement"). Exhibit 5. That Agreement has a term of five years. 2010 Agreement, p.1, § 1 and expired seven years ago.

MDOT has told Pittsfield that there have been no amendments to the Agreement between MDOT and the Federal Aviation Administration (FAA), and a new Agreement has not been executed. Michigan is out of compliance with 49 U.S.C. § 47128 which requires such agreements to be in place before the FAA can fund the state's block grant program. See 49 U.S.C. § 47128(b)(4) and (5). MDOT seems to have lost its ability to fund the Project. See Financial/Economic response #13

When a project is undertaken under the SBGP, federal law requires the Michigan Department of Transportation ("MDOT") to follow "United States Government standard requirements for administering the block grant, including the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.), State and local environmental policy acts, Executive orders, agency regulations and guidance, and other Federal environmental requirements." 49 U.S.C. § 47128(4) (emphasis added).

Thus, as a matter of federal law, in carrying out projects under the SBGP, MDOT must comply not only with NEPA, the Clean Air Act, the Clean Water Act, CERCLA and RCRA, and as all state and local laws, in addition to FAA orders, regulations and guidance.

If the 2010 Agreement is still in effect, the requirement of 49 U.S.C. § 47128 that MDOT follow federal, state, and local law is also a matter of contract, as stated in the 2010 Agreement between the FAA and MDOT.

> In carrying out this program, MDOT will comply with all Federal laws, regulations and executive orders set forth in Attachment B. MDOT also acknowledges awareness of FAA policy and guidance in the form of Orders which have applicability to the state block grant program and are set forth in Attachment B.

2010 Agreement, p.3, Exhibit 5. "Attachment B" lists the federal statutes, rules, and regulations that MDOT must follow when carrying out projects, such as the proposed action.

In addition to federal law, projects under the SBGP must also follow state laws as well. 49 U.S.C. § 47128(4). This means this project must comply with the Michigan Environmental Protection Act ("MEPA"). MCL.324.1701 – 1705. MEPA prohibits state agencies, such as MDOT, from authorizing projects that will result in the "pollution, impairment, or destruction of the air, water, or other natural resources, or the public trust in these resources." MCL 324.1705(2). There is no indication in the SRDEA that it follows Michigan environmental laws, regulations, and standards. MEPA indicates that it is incumbent on MDOT to show that "there is no feasible and prudent alternative" to the Project and that its conduct is consistent with "the promotion of the public health, safety, and welfare in light of the state's paramount concern for the protection of its natural resources from pollution, impairment, or destruction." MCL 324.1703(1). If MDOT approval of this project allows conduct that harms the air and water, and increases noise pollution, and invades the public trust in these resources, which it does, it does not comply with MEPA. See General response #28

In proposing the Project, MDOT's project must also follow local ordinances as well. 42 U.S.C. § 47128. there is no indication in the SRDEA it will comply, for example, with Pittsfield Township's Noise Ordinance. Pittsfield Township, within which ARB is located, has a long-standing noise ordinance making it unlawful for "any person to create, assist in creating, permit, continue, or permit the continuance of any unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township." Exhibit 6. MDOT and the SRDEA must make sure that Pittsfield Township's citizens' health, safety and property are protected from "unreasonably loud, disturbing, unusual or unnecessary noise" created by the Project. *Id*. In addition, Pittsfield contracted with the City of Ann

Arbor regarding ARB. Exhibits 7 & 8. There is no indication in the SRDEA, ARB and MDOT will follow the Agreement between Pittsfield and the City of Ann Arbor.

See Noise response #1, #4, & #13

III. The SRDEA Does Not Support Its Purpose and Need Because There Is No Purpose or Need for the Project

An environmental assessment (EA) must include a discussion of the purpose and need for the proposed action which must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." 40 C.F.R. § 1502.13; see also, 40 C.F.R. § 1502.14; *Nat'l Parks & Conservation Ass'n v.BLM*, 606 F.3d 1058, 1070 (9th Cir. 2010); *Westlands Water Dist. v. United States*, 376 F.3d 843, 865, 867 (9th Cir. 2004). In addressing the Purpose and Need section of an EA, FAA Order 1050.1F provides that the Purpose and Need section "presents the problem being addressed and describes what the FAA is trying to achieve with the proposed action. The purpose and need for the proposed action must be clearly explained and stated in terms that are understandable to individuals who are not familiar with aviation or commercial aerospace activities." FAA Order 1050.1F, ¶ 6-2.1c. The SRDEA's Purpose and Need accomplishes none of these goals.

The "need" is the problem, and the "purpose" is the proposed solution to the problem. The Purpose (*i.e.,* the Project) is supposed to resolve the Need (*i.e.,* the problem). Here, it is the opposite, one large tenant's desire (AvFuel Corp.) to extend the runway is driving the proposed action. This is a case of a Purpose looking for a Need. It is a project looking for a problem to justify its existence.

See General responses #3 and #14.

A. Neither the Purpose nor the Need justify the harm done to the communities surrounding ARB

In this third iteration of the environmental assessment, MDOT and ARB have abandoned any pretense that extending the runway at ARB is for safety reasons. Instead, the purpose of the runway extension is simply to "improve operational utility of the airport by meeting the takeoff and landing runway length requirements of aircraft that currently operate at the airport and are projected to steadily increase over time." SRDEA, p. 1-7. The SRDEA states that the Project is needed "because the Runway 6/24 was designed to serve primarily small piston driven aircraft; [sic] however, the Airport receives regular use by small turboprop aircraft and occasional business jet aircraft that require a longer runway to operate at a greater payload than they do today." Neither the purpose nor the need justifies the harm to the public health and safety of the surrounding neighborhoods that the extension to the runway will create. After reviewing the SRDEA and the "Runway Justification Study," it is apparent that the "purpose and need" for the Project is to allow a handful of larger aircraft operators at ARB to operate with full payloads on a couple of hot, humid days.

See General responses #3 and #14; Safety/Health responses #3 and #9; and Safety/Health responses #11 and #15.

1. The SRDEA incorrectly categorizes B-II as the "critical aircraft" for Runway 6/24

The SRDEA claims that the critical aircraft at ARB is "B-II." "B-II" denotes an aircraft with an approach speed of 91 nautical miles per hour ("NMPH"), but less than 121 NMPH, (Aircraft Approach Code of "B"), wingspan of 49 ft., but less than 79 ft., and a tail height of 20 ft., but less than 30 ft. (Aircraft Design Group "II").

To determine the "critical aircraft," the SRDEA states that it "may be a single type of aircraft or a grouping of types of aircraft with similar characteristics that conducts at least 500 annual operations at an airport." SRDEA, Appendix C, p.19. It claims that the "B-II" grouping of aircrafts represent the "critical aircraft" at ARB. *Id.* The SRDEA claims that in 2019 there were 679 B-II operations, *Id.,* and, therefore, B-II is the "critical aircraft" for Runway 6/24.

FAA's AC 150/5000-17, *Critical Aircraft and Regular Use Determination*, however, states that in determining the "critical aircraft" for the airport, "an operations count by aircraft make and model is required for the **most recent 12-month period of activity** that is available." AC 150/5000-17, p.2-1 (emphasis added). Since the Runway Justification Study was run in February 2021, the "most recent 12-month period of activity" would have been from February 1, 2020, until January 31, 2021. According to the FAA, there were 383 B-II operations at ARB during that period. *FAA Traffic Flow Management System Counts,* *https:/aspm/faa.gov/tfms/sys/Airport.asp*. The last full calendar year of data available to MDOT in February 2021 showed that in 2020 there were 424 B-II operations from ARB. *Id.* If one were to use the date that SRDEA was issued (November 13, 2022), one arrives at 469 annual B-II operations. *Id.* The SRDEA provided no justification for using data from 2019, which is not allowed using FAA's criteria in its Advisory Circular. See Technical response #8 and #10

To cover up the failure to reach the required 500 annual operations within the previous 12-month period, SRDEA uses false numbers to bolster its argument that B-II is the "critical aircraft" at ARB. Table 1-0 in the SRDEA (p.1-8), for example, which shows the number of B-II flights is wrong. When compared to the chart in the Appendix C, the "annual operations" numbers in Table 1-0 are wrong.

Representative Aircraft	**Annual Ops 2019 in Table 1-0 of SRDEA**	**Actual Annual Ops from FAA TFSMC Database**
TBM8 (Socata TBM 850)	150	90
BE20 and B350 (Beechcraft King Air)	966	264
C56X (Cessna Excel XLS)	263	161
E55P (Embraer Phenom 300)	97	77
C172 (Cessna 172)	2,876	709
EC55 (EC-155)	84	82

This verifiably false information in the SRDEA calls into question the veracity of all data in the SRDEA and is a violation of NEPA. *See* 40 C.F.R. § 1502.24. Because of this, MDOT cannot be trusted to present correct data about the situation at ARB based on its willingness to use false data for such a critical issue.

Therefore, the SRDEA's conclusion that "B-II" aircraft are the "critical aircraft" for Runway 6/24 at ARB is wrong. Because the Airport Reference Code "B-II" is not the critical aircraft, the runway does need not be lengthened to accommodate that size of aircraft. See Technical response #11

2. Use of the lengthened runway would rarely be required, but would pose substantial risks to the surrounding community every day

a. After over twelve years, MDOT and ARB still have presented no evidence of "undue concessions"

The SRDEA claims that an extended runway is needed because for small turboprops and jets "to conduct operations on the existing runway, undue concessions in reduced fuel, passengers and/or cargo loads are often needed." SRDEA, p. 1-7. This has been the primary justification for extending the runway since 2007. However, none of the inventories, assessments, analyses, or studies required by FAA Order 1050.1F are present in the SRDEA that would confirm this need. FAA Order 1050.1F, ¶ 6-2.1c. As the FAA pointed out in an earlier draft of the SRDEA, "[t]he rate of users taking weight restrictions has not been documented (at least in the justification report)." Exhibit 13. Neither the SRDEA nor the Runway Justification Study (Appendix C of the SRDEA) provide any documentation regarding the weight restrictions experienced by any aircraft at ARB. In response to the FAA and community concerns, MDOT and ARB simply brush the issue off by claiming that because they have gathered no data, they can provide no documentation about this critical issue. See SRDEA, Appendix N, p. 18, ("There is no information available on the number of aircraft operations that have needed to make weight and/or fuel concessions to operate at ARB. This is because there are no publicly available databases with this information. Likewise, there are no methods to obtain an accurate count of this number since all pilots would need to be willing to participate in an interview/survey effort to share this information"). There is no evidence or discussion in the SRDEA that operating with weight restrictions is an issue at ARB for anyone except the pilot of the Citation XLS.

Although no evidence indicates that airport users are taking "undue concessions," MDOT leans heavily on this purported "need" in the SRDEA. MDOT frequently mentions it throughout the SRDEA as the justification for extending the runway. Yet, although this has been an issue for over twelve years, neither MDOT nor ARB has tried to gather the information requested by the FAA and the surrounding communities. MDOT and ARB have even failed to gather this information from the two aircraft that account for most of the B-II flights. Without that evidence or other support, the statements made by MDOT regarding the purported "need" are unreliable and self-serving and must be dismissed as arbitrary and capricious.

Even B-II aircraft must take weight restrictions on a "regular basis," MDOT still has not answered FAA's logical and reasonable question from 2016: "Why do they base at ARB instead of another close airport if they cannot use the aircraft to its max capability?" (Comment No. 15, October 2016 MDOT AERO/Applicant Ann Arbor comments in response to FAA questions) Exhibit 9. Why, indeed.

As mentioned above, MDOT claims that the Project is needed "because the Runway 6/24 was designed to serve primarily small piston driven aircraft; [sic] however, the Airport receives regular use by small turboprop aircraft and occasional business jet aircraft that require a longer runway to operate at a greater payload than they do today." Exhibit 13. This putative need, however, presumes that such critical aircraft cannot already operate at such capabilities regularly. Again, the SRDEA presents no evidence that aircraft currently operating at ARB have incurred weight penalties. On the few occasions that a longer runway is needed, Willow Run Airport (YIP) is a short 12 statute miles from ARB (about 15 minutes by car). YIP has three runways (7500, 7300 and 6000), 24-hour tower, 24-hour fire and rescue, de-icing, and robust general aviation and business aviation facilities. Thus, the Airport's argument that the runway needs to be lengthened so a handful of aircraft pilots and passengers need not drive an extra 12 miles to get to/from the airport on the few days that a weight restriction would be required is ludicrous when compared to the damage the increase in jet operations will do to surrounding communities.

This issue of justification of the need to lengthen the runway has been problematic since the idea was first raised in 2007. Even the FAA has questioned the need for an extended runway. In May 2010 comments on the 2010 Draft Environmental Assessment (DEA), the FAA asked, "[h]as it been documented that the current B-II 'small' users operate with load restrictions? If so, how often does this occur and what are the quantifiable impacts to their operations?" Exhibit 10. In the ensuing 12 years, ARB has never answered the FAA's question from 2010 by providing that documentation. In addition, in a separate question, the FAA asked, "the conclusion for the implementation for the preferred alternative states that a positive result of improvements is the ability of business owners to achieve improved fleet efficiency for critical aircraft by maximizing their passenger and/or cargo loads. How has this statement been substantiated? What records exist that current users at ARB are not operating at maximum passenger and/or cargo loads? What has been the economic impact of the reduction of loads if they are occurring?" To paraphrase the FAA's questions, if there is no established, substantiated loss of passenger or cargo load opportunities, or established current negative economic impact, there is no Need. These questions must be answered before any project to lengthen the runway is even considered by MDOT. The SRDEA does not have answers to these questions. Since these questions have been pending for 13 years

It is also worth noting that MDOT's federal block grant status could be at risk if it does not enforce the requirements under FAA Order 1050.1F in terms of requiring applicants to provide supporting data, inventories, assessments, analyses, or studies to support its proposed expansions, even though MDOT has not traditionally done so. Since this question is so important to the justification for lengthening Runway 6/24 at ARB, without evidence to support the statement that existing aircraft are taking weight penalties "on a regular basis," any decision to move forward with the Project is arbitrary and capricious. See Technical response #7

b. "Contaminated runway" is not a justification for lengthening it

The SRDEA also claims that the runway extension is needed because "[d]iversions to other airports are also commonly needed when the runway surface is wet, or during the summer months when higher temperatures reduce aircraft performance." SRDEA, p. 1-7. This is contrary to the Runway Justification Study, which states in Section 6.3 that "The inclusion of the contaminated runway length distances cannot be used to justify runway length under FAA funding requirements …" SRDEA, Appendix C, p. 26. FAA also pointed this out in its comments, stating "[r]ecommend clarifying that contaminated runways are not used in the runway length requirements." FAA Comments, p.1-5. MDOT ignored both the Runway Justification Study and the FAA and included the sentence as part of the justification for the "need" for the Project. See Technical response #7

c. A longer runway is not needed to accommodate the existing aircraft that use ARB

The "purpose and need" of the Project comes under additional scrutiny when one considers that the take-off/landing distances specified for the various B-II aircraft that regularly use ARB. Since the "need" is to allow airport users to conduct operations without "undue concessions in reduced fuel, passengers and/or cargo loads," (SRDEA, p. 1-7), it is important to understand what are the "operational performance characteristics" for B-II aircraft that regularly use ARB. The following table is a table of the Take-Off Distance and the Landing Distances for the B-II identified in the Appendix C of the SRDEA.

Aircraft Model	No. of 2019 Operations	Take-off Distance (MTOW, Sea Level, ISA) (feet)	Landing Distance (feet)
Gulfstream Jetprop Commander 1000	4	2,131	2,186
Beech Super King Air 350	123	3,300	2,692
Beech 200 Super King Air	141	2,579	2,074

Raytheon 300 Super King Air	2	3,300	2,692
Beech F90 King Air	2	2,775	
Cessna 208 Caravan	100	2,053	1,624
Cessna Citation CJ4	5	3,180	2,770
Cessna Conquest	2	2,465	1,875
Cessna Citation II/Bravo	8	3,450	2,078
Cessna Excel/XLS	161	3,590	2,909
Cessna Citation Sovereign	28	3,530	2,600
Embraer Phenom 300	77	3,199	2,430
Pilatus PC-24	21	2,930	2,375

SRDEA, Appendix C

While the Cessna Citation Excel and the Cessna Citation Sovereign may not be able to operate at their maximum weight on an average day, they could operate at about 90% of their maximum weight. All other "B-II" aircraft can use ARB's 3,505-foot runway with little or no weight restrictions on most days. The Beechcraft King Air 200 can use ARB's 3,505-foot runway on most days without weight restrictions. The entire runway expansion project is specifically designed to benefit a single aircraft: AvFuel's Cessna XLS. See Technical response #2

As stated above, ARB has long claimed that an extended runway is needed because the small turboprop and jet aircraft operating out of ARB "on a regular basis" suffer "undue" weight penalties due to the length of the runway. While neither MDOT nor ARB have provided any data about how often this occurs, it is possible to provide a rough statistical analysis based on usage data of how the expanded runway might be necessary. FAA Advisory Circular 150/5325-4B *Runway Length Requirements for Airport Design,* Exhibit 11, aids an airport in determining the recommended runway length. AC 150/5325-4B, has a runway length curve used with temperatures at 86ºF (30ºC) or above, and an ARB elevation of 839 feet to meet the mean daily temperature during the hottest month at ARB. ARB had 76,430 total operations in 2019, of which, MDOT claims (at least in Appendix C, if not in the text of SRDEA) 679 were category B-II operations. SRDEA, Appendix C, pp. 8, 19. An analysis of data from the National Oceanic and Atmospheric Administration Weather Station at ARB shows that in 2019 there were 66 days in which the temperature was 86ºF or above. ARB has a based population of 164 aircraft, of which 14 are category B-II aircraft.

With these data, a calculation of potential need of an expanded runway based on maximum potential need can be made. If, on every day on which the temperature reached or exceeded 86 degrees, every aircraft in the B-II fleet attempted to operate at its maximum take-off weight – a highly unlikely possibility – and required the expanded runway to take-off, based on the ARB fleet population the need for the expanded runway would be 0.0154, or 15 in 1,000 (66/365 x 14/164). This means that for every 1,000 operations at ARB on a day over 86º, only 15 operations would be B-II aircraft. This is based on the number of days with temperatures exceeding 86 degrees and the proportion of the total ARB fleet that is Category B-II.

However, if this calculation were based on the more realistic actual usage in the operational year used by MDOT (2019), on every day the temperature reached 86 degrees or above, the actual need for an expanded runway would be 0.0016 – or about 1.6 B-II operations for every 1,000 operations (66/365 x 679/76,430) – the number of B-II operations relative to the total operations in SRDEA's study year 2019. In addition, weight penalties are more of a concern for take-offs, rather than landings. So, the issue would apply primarily to one-half of the "total operations" for B-II aircraft, or about 340 operations per year. This lowers the actual "need" for the runway extension to 8 B-II operations for every **10,000 operations** on a day over 86º (66/365 x 340/76,430). See Technical response #4 & #5 and General response #3 and #14

Thus, operational need for an expanded runway would be rare. Based on statistical analysis the expanded runway would be necessary for about 42 operations per year, at most. Yet, it would place citizens in the surrounding community at risk hundreds of times more often because aircraft would take off and land 950 feet closer to residential areas, and larger and heavier aircraft will be attracted to ARB by the expanded runway. The area to the west and south of the Airport – just off the most frequently used end of the runway – is heavily residential. The Airport is not in a rural setting and more homes are being constructed close to the Airport. These risks are exacerbated because of the potential dangers posed by aircraft that would land just 93 feet over homes in an area heavily populated with Canada geese just west of the airport, and by the reduced margins of safety if an aircraft suffers an engine failure on or just after takeoff. Such aircraft can lose their climbing power with an engine loss and could crash into the heavily populated neighborhood. The risk of – and liability from – such a potential accident has not been studied and should be as part of any assessment about the purpose and need of extending the runway at the Airport.

See Noise response #3 & Safety/Health responses #1, #2, and #3

3. The lengthened runway would primarily benefit a handful of rich, well-connected aircraft operators.

AvFuel, a Pittsfield Township-based national aviation fuel supplier that counts ARB as one of its customers, would be the primary beneficiary of any runway expansion as owner and operator of B-II aircraft based at ARB. AvFuel provided a letter of support in the SRDEA, claiming that, "most flights departing ARB require concessions to fuel and/or passenger loads with a stop for fuel before reaching their intended destination due to runway length limitations at ARB. When runway 6/24 is contaminated with snow or ice, AvFuel often needs to divert to another airport, which delays or cancels flight plans until pavement surface conditions at ARB improve, since braking distance is reduced when water, snow, or ice is present," SRDEA, Appendix C, p. B2, although no specific data on any such impacts were provided.

In addition, a further analysis based on aircraft performance data provided in the SRDEA's Runway Justification Analysis confirms that the Citation-class aircraft, including AvFuel's Cessna Citation XLS jet, could operate 90% of the time on the existing 3,505-foot runway. The Citation XLS performance data shows only a 3,500-foot runway is required until temperatures exceed 85 degrees F., which would let the AvFuel jet operate at 90% capacity. SRDEA, Appendix C, pp. E13-14. Also, in response to claims of the need for a longer runway to combat wet runway conditions, the FAA noted that under such circumstances, "Safety is maintained by the pilot adjusting their mission (payload, etc.) to the available runway length, not by the addition of a longer runway."

To further support the claimed need for the extension, the SRDEA explains that the 4,649 instrument flight rules (IFR) operations at ARB in 2019, indicating the aircraft involved required eliminating weight concessions that would let aircraft operate at greater capacity, thus resulting in a "more efficient operating environment." However, further analysis of the supporting data showed that all but an estimated 48 Citation XLS class jet flights of the 4,525 IFR airplane operations could be conducted on the current 3,505-foot runway without penalty.

Finally, if operating the aircraft to fullest extent of its capabilities is such a concern, then the owners of the aircraft should move their aircraft to YIP – just a few miles from ARB. While that may be inconvenient for the owners of the handful of aircraft it would affect, that inconvenience pales when compared to the damage that would be done to the public's health and safety should the runway be lengthened.

See General response #3, #13, and #14

4. Support for Need for Economic Need and Increase in Jet Operations Comes at a Cost.

In support of the presumed need, and alluding to a connection between the airport and the Ann Arbor-area business community, the SRDEA also reported that the area surrounding Ann Arbor was home to "many prominent businesses and institutions with the University of Michigan being the area's largest employer. Manufacturing, health care, automotive, information technology, and biomedical research companies account for major employers in the surrounding area." SRDEA, pp. 1-1. The SRDEA added that with many such technology-driven industries, "[t]here is often a need for air transportation to bring workers, clients, suppliers, customers, and time sensitive parts / supplies to and from the region." SRDEA, p. 1-2. However, no data were provided to support the implied claims of any connection to or the vitality of ARB to support such vast economic and operational activity, save for particulars on the AvFuel XLS Citation jet. In addition, the SRDEA does not address the fact that YIP can satisfactorily address the needs of the surrounding area, since there are very few "businesses and institutions" that are not also within a short drive from YIP. See Financial/Economic response #12

The SRDEA suggests that the University of Michigan's six/seven home football weekends each year and the two annual NASCAR racing events at nearby Michigan International Speedway are examples that bring increased aircraft activity to airports in the region, suggesting that "should Runway 6/24 be extended, additional aircraft activity could occur at ARB due to its proximity to special event venues surrounding the Ann Arbor area." Again, any need for more airport capacity can be (and has been) satisfactorily met by YIP. For example, according to Google Maps, YIP is just 8.8 miles further from Michigan International Speedway (ARB is 33.9 miles away, and YIP is 42.7). Even the comparative distance between the two airports and Michigan Stadium is inconsequential. While ARB is 3.6 mile (or 4.3 miles) from the stadium, YIP is only 13.6 miles away from the stadium. It is not apparent from the SRDEA why residents in the surrounding communities would have suffer health impacts just so a few wealthy aircraft owners can shave 5 minutes off their drive to downtown Ann Arbor or Brooklyn, Michigan. See Technical response #3

An earlier draft of the SRDEA projected an immediate tripling of annual jet operations if the ARB runway were extended to over 1,000 operations per year, with another 500-665 operations from jets, which use nearby Willow Run Airport, possibly moving to an expanded ARB. That earlier draft SRDEA suggested that up to 40% of the current 9,313 annual small and medium jet operations at nearby Willow Run Airport "would likely shift to ARB if additional runway length were available," thus increasing jet operations from the 360 in 2019 to upwards of 3,660 jet operations per year – a 10-fold increase, ultimately turning ARB into a jetport. This is not an organic increase in jet operations. This is a shift of operations from YIP to ARB. This indicates that the extension of the runway would not increase air traffic in the region – thereby increasing the economic benefit to the region – but merely shift jet operations from YIP to ARB. Even AvFuel Chief Pilot suggests that, indicating that AvFuel would shift its aircraft currently based at YIP to ARB. Were YIP operating at capacity or near capacity, this would be a benefit to the region. But it is not. YIP has the available capacity to safely and efficiently handle any aircraft that cannot take-off or land at ARB due to "operational capabilities," now and in the future.

In short, the "need" expressed in the SRDEA is being already being met by YIP. There is no need for ARB to extend its runway. See Technical response #4

IV. The Use of Willow Run Airport Is a "Reasonable Alternative" that Has Not Been Fully Considered.

The National Environmental Policy Act ("NEPA") (42 U.S.C. §§ 4321 *et seq.*) requires that federal agencies examine all reasonable alternatives in preparing environmental documents. 42 U.S.C. § 4332(c)(iii). An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action is intended to address. The Council on Environmental Quality ("CEQ") Regulations ("NEPA Regulations"), which implement NEPA, require that Federal agencies "[u]see the NEPA process to identify and assess the reasonable alternatives to the proposed actions that will avoid or minimize adverse effects of these actions upon the quality of the human environment" 40 C.F.R. § 1500.2(e), and that "agencies shall . . . (a) Rigorously explore and objectively evaluate all reasonable alternatives…." 40 C.F.R. § 1502.14(a). Courts have consistently held that the "existence of reasonable but unexamined alternatives renders an EIS inadequate." *See*, *e.g.*, *Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998). The FAA and MDOT must act if an environmental assessment is limiting the choice of reasonable alternatives. "If the FAA is . . . aware that the applicant is about to take an action within the agency's jurisdiction that would have an adverse environmental impact or limit the choice of reasonable alternatives, the responsible FAA official will promptly notify the applicant that the FAA will take appropriate action to ensure that the objectives and procedures of NEPA are achieved" 1050.1F, 2-3.1. Because the SRDEA fails to explore all reasonable alternatives to the Preferred Alternative selected, it is inadequate.

The SRDEA does not address using Willow Run Airport (YIP) as alternative. The SRDEA bases its conclusion that ARB is a more "desirable" location on the assumption that B-II aircraft operators using ARB instead of YIP "demonstrates that a large number of operators of business aircraft value the close proximity of ARB to their corporate offices and business contacts over the larger facility at Willow Run." SRDEA, Appendix N. This is a baseless assumption since it is equally likely that the fact that B-II aircraft still land at ARB instead of YIP because the weight restrictions posed by the short runway ARB are non-existent or not significant, otherwise these users would land at YIP instead.

Although the FAA raised this point in its October 2016, comments, the SRDEA chose not to address it. FAA October 2016, Comments, No. 62. Exhibit 9. Instead, ARB waves the argument off by stating that the Airport "cannot dictate which airfield a pilot uses" – an argument that applies equally to the SRDEA's argument that rejects the YIP alternative.

However, using YIP instead of ARB meets the purpose and need of the project thereby making it a reasonable alternative that must be considered in the Environmental Assessment. That is, the operational requirements of all of the aircraft at ARB can be met by using YIP instead of ARB. As the SRDEA points out, YIP has the runway length and facilities to accommodate the aircraft that may be weight-restricted from using ARB. The only reason that the SRDEA does not consider YIP as a reasonable alternative is that it is located and mere 12 miles from ARB and that it is slight inconvenience to the corporations who want to use ARB instead of YIP. Even if lengthening the runway would benefit more than one or two aircraft, this is not an appropriate reason to dismiss an alternative from further consideration in an Environmental Assessment. If an alternative is "reasonable" (*i.e.,* it meets the purpose and need) then it must be considered in the Environmental Assessment alongside the preferred alternative and the no action alternative. *Friends of Southeast's Future v. Morrison,* 153 F.3d 1059, 1065 (9th Circ. 1998). Since using YIP instead of ARB would achieve the purpose and need of allowing "critical aircraft" to take-off and land without weight restrictions, it is a reasonable alternative and must be considered as part of the Environmental Assessment process. The SRDEA must be considered inadequate, arbitrary, and capricious on this basis alone.

See General responses #5 & #10 and Financial/Economic response #11

V. ENVIRONMENTAL IMPACTS

United Stated federal law states at 49 U.S.C. § 47101(a)(6) that it is "the policy of the United States . . .that airport development under this subchapter [which includes the SBGP] provide for the protection and enhancement of natural resources and the quality of the environment of the United States." NEPA, the NEPA regulations, caselaw, other applicable environmental laws, state, and local law provide the framework for carrying out this policy. At a bare minimum, an environmental assessment must describe the impact the proposed project will have on a variety of environmental resources. The Project will have a significant impact on the environment not only on the airport, but throughout the surrounding communities. Since it is Pittsfield's duty and responsibility to protect the environment within its boundaries and to protect its residents from significant environmental impacts, it has serious concerns about the environmental impact the Project will have on the community.

See Safety/Health responses #11 and #15, Water Resource/Water Quality response #1, and Air Quality response #1

A. NEPA requires that a Health Risk Assessment be drafted for the Project

NEPA requires agencies to analyze the direct and indirect environmental consequences that a proposed action might have on public health and safety. 40 C.F.R. §§ 1501.3(B)(2)(III), 1502.16(a) – (b), 1508.1(g). An agency normally meets this statutory requirement by preparing a health risk assessment ("HRA") or other comparable study that is subject to a public comment and review process to ensure all "likely health effects" are "adequately disclosed." *Natural Resources Defense Council, Inc. v. U.S Dept. of Transp.*, 770 F.3d 1260, 1272 (9th Cir. 2014); *see also Beverly Hills Unified School District v. Federal Transit Administration*, No. CV- 12-9861-GW (SSX) 2016 WL 4650428, at *61 (C.D. Cal., Feb. 1, 2016). The SRDEA fails to take a hard look at the Project's environmental impacts by failing to include an

HRA or any comparable analysis and provides no support for the health and safety conclusions made in SRDEA § 3.15.3. See Safety/Health response #17

As a threshold issue, the SRDEA's analysis is improperly constrained to consideration only of health impacts to children. See SRDEA § 3.15.3. NEPA does not limit an agency's health impact analysis to just children, however. Rather, it mandates an agency consider "the degree of [a proposed action's] effects on public health and safety." 40 C.F.R. § 1501.3(b)(2)(iii), emphasis added. The Environmental Protection Agency's ("EPA's") guidance advises agencies to assess health impacts for all "population groups of concern." See Safety/Health response #4

An HRA for a proposed action of this size and scope should include, at least, emissions estimations of hazardous air pollutants ("HAPs"), exposure assessments, dose-response assessments, and a potential health risk measurement. This requires consideration of all construction and operational sources of emissions, including on- and off-road equipment, and emissions/toxins associated with construction. In addition, the SRDEA does not mention whether firefighting foam was or is used at ARB that may contain per- and polyfluoroalkyl substances (PFAS) and/or other toxic materials, such as perfluorononanoic acid (PFNA), perfluorooctanoic acid (PFOA), and perfluoroctanesulfonic acid (PFOS). If it was or is used at ARB, those substances may be in the soil unearthed as of part of the Project and is now in the groundwater. Likewise, the aviation gas that is stored at ARB contains lead, among other hazardous components, yet the SRDEA does not analyze whether disturbing the soil will cause lead to leach into the ground. In addition, the soil underneath and around the Airport likely contain other federally regulated substances, such as volatile organics, semi-volatile organics, PCBs, metals, pesticides, and petroleum hydrocarbons. The task of removing and remediating this contamination, alone, should be subject to an HRA-style analysis before the construction phase begins.

See Air Quality responses #1 & #2; Water Resources/ Water Quality responses #1 & #4

Nearly all of the over twenty individual exhaust constituents are regulated as HAPs by the Federal Clean Air Act. 42 U.S.C. § 7412(b). The SRDEA should include an HRA that analyzes potential health impacts from construction activities, on-going airport ground operations (ground support equipment, emergency generators, truck deliveries, etc.) and aircraft operations. Exhaust from these sources contains benzene, formaldehyde, PAH's, naphthalene, acetaldehyde, acrolein, 1,3-butadiene, chlorobenzene, propylene, xylene, ethyl benzene, arsenic, cadmium, chromium, lead, manganese, mercury, nickel, and selenium. These toxic contaminants must be analyzed in the SRDEA in relation to human health.

See Air Quality responses #1, #3, and #4

The SRDEA, to be transparent and informative as required by NEPA, should have an HRA that includes the aforementioned sources and associated risks to human health. An HRA is critical for ensuring an adequate disclosure of the Project's health effects to the public and decisionmakers. *Natural Resources Defense Council, supra*, 770 F.3d at p.1272.

When preparing the HRA for the Project, the study area should be expanded to include a broader range of sensitive receptors. A two-mile radius to pick up additional sensitive receptors such as schools, hospitals, and parks should be used. Construction-related emissions such as diesel construction trucks and soil hauling would be expected to impact areas over two miles away because of their operational characteristics and haul routes. And aircraft exhaust and noise from the increase in aircraft operations and change in the type of aircraft using the Airport will also affect an area considerably larger than the project area.

A Health Impact Assessment or similar public health analysis should be part of the ARB environmental analysis. Failing to include a Health Risk Assessment would render the environmental assessment arbitrary and capricious.

B. Noise from aircraft, particularly high-performance jets has not been sufficiently analyzed by MDOT.

1. Technical and Scientific Data Support the Finding that Aircraft Noise is Detrimental to Public Health and Welfare.

a. Aircraft noise has caused health risks to people living under flight paths.

i. Aircraft noise causes an increased risk of cardiovascular disease, hospitalizations, and mortality.

The causal connection between aircraft noise and this increased health risk is well-supported by a growing body of scientific evidence. Two large studies have found associations between aircraft noise and heart disease and stroke. In a 2013 Harvard University study, researchers examined hospitalization rates in 6 million adults aged 65 years and over living near 89 US airports. The study concluded there is a statistically significant association between exposure to aircraft noise and risk of hospitalization for cardiovascular diseases among older people living underneath flight paths.[1] A second 2013 study examined hospitalization and mortality in a population of 3.6 million potentially affected by aircraft noise from London Heathrow airport.[2] The conclusion in that study was that aircraft noise was associated with increased risks of stroke, coronary heart disease, and cardiovascular disease for both hospital admissions and mortality.

Two additional studies discussed below have found connections between aircraft noise and heart disease and stroke. In one study, using data collected between 2004 and 2006 on 4,712 participants who lived underneath flight paths in six European countries, researchers concluded that individuals exposed to aircraft noise over many years showed an increased risk of heart disease and stroke.[3]

Likewise, a census-based study of 4.6 million individuals in Switzerland concluded that aircraft noise was associated with mortality from myocardial infarction.[4] The study noted that the association does not seem to be "explained by exposure to particulate matter air pollution, education, or socioeconomic status of the municipality."

ii. Aircraft noise causes an increased risk of hypertension.

Besides causing cardiovascular disease, aircraft noise is also linked to an increase in hypertension among those exposed. Two meta-analyses[5] relating to seven epidemiological studies found a correlation between aircraft noise exposure and hypertension in adults.[6] A 2008 field study of 140 individuals living near four European airports found increases in blood pressure during the night sleeping period related to aircraft operations.[7] Short-term experimental studies in healthy

adults[8] and those with existing cardiovascular disease[9] have found links between aircraft noise at night and next-morning blood pressure and blood vessel functions.

iii. Aircraft noise increases the risk of dementia in older individuals.

Besides an increased risk of cardiovascular disease and hypertension, a recent study confirms that aircraft noise also causes an increased risk of developing dementia later in life.[10] "These findings suggest that within typical urban communities in the United States, higher levels of noise may impact the brains of older adults and make it harder for them to function without assistance. This is an important finding since millions of Americans are currently impacted by high levels of noise in their communities," said senior author Sara D. Adar, ScD, of the University of Michigan School of Public Health, Ann Arbor.[11] Professor Adar added that "although noise has not received a great deal of attention in the United States to date, there is a public health opportunity here as there are interventions that can

reduce exposures both at the individual and population level." *Id.* This study underscores the need for FAA to reduce exposure to aircraft noise to better protect older adults living in Pittsfield Township. See Safety/Health response #11 & #15

b. Aircraft Noise Causes Sleep Disturbance for Those Who Live Under the Flight Paths.

"Sleep undoubtedly counts as one of life's basic needs," the court concluded in *Harper v. Showers*, 174 F.3d 716, 720 (5th Cir. 1999). The Second Circuit agreed that "[n]o reasonable person would disagree that "sleep is critical to human existence." *Walker v. Schult*, 717 F.3d 119, 126 (2d Cir. 2013). Sleep is a biological imperative, and an active process that serves several vital functions for human life. Undisturbed sleep of sufficient length is essential for daytime alertness and performance, quality of life, and health.[12] The epidemiologic evidence that chronically disturbed or curtailed sleep is associated with negative health outcomes (such as obesity, diabetes, and high blood pressure) is overwhelming. Aircraft noise-

In recognition of the significant environmental risk from noise pollution, European Parliament and Council adopted Directive 2002/49/EC of 25 June 2002 to manage environmental noise. *Id.* In turn, the EU Parliament has mandated all EU Member States to develop a noise map and action plan to manage noise as evidence regarding the health effects of environmental noise has mounted in the recent years. *Id.*).

Muzet A, *Environmental noise, sleep, and health*, 11 Sleep Med. Rev. 135 (2007). Exhibit 27.

induced sleep disturbance is considered the most deleterious non-auditory effect of aircraft noise.

In 2012, researchers conducted a systematic review to clarify the causal link between aircraft noise exposure and sleep disturbance.[13] The researchers reviewed 12 studies that dealt with sleep disturbances. Of those studies surveyed, four were found to be of high quality, five were considered of moderate quality and three were considered of low quality. All moderate- to high-quality studies showed a link between aircraft noise events and sleep disturbances such as awakenings, decreased slow wave sleep time or use of sleep medication.

Four years later, in 2016, researchers investigated the relationship between sleep disturbance and exposure to aircraft noise on almost 4,000 residents living near an airport.[14] The study concluded that the prevalence of insomnia and daytime hypersomnia (excessive daytime sleepiness) was higher in the aircraft noise exposure group, as compared to the control group. The study concluded there is a causal relation between exposure to aircraft noise and sleep disturbances.

Research has shown a relationship between aircraft noise exposure and sleep disturbance and a link between noise-induced sleep disturbance and long-term

Exhibit 29.

health consequences. The residents underneath flight paths are now waiting for the policymakers to help mitigate the effects of aircraft noise on their sleep.

See Safety/Health response #12 & #15

c. Aircraft Noise Has an Impact on Children's Learning and Low Weight at Birth.

The aircraft noise generated by aircraft flying above Pittsfield Township will affect children living underneath flight paths. Recent studies show that children born to mothers living underneath flight paths are born with lower-than-normal birth weight. See Safety/Health response #4

i. Chronic exposure to aircraft noise negatively affects children's ability to learn.

Reviews of how noise, and in particular aircraft noise, affect children's learning have concluded that aircraft noise exposure at school or at home is associated with children having poorer reading and memory skills.[15] There is also increasing evidence suggesting that children exposed to chronic aircraft noise at school have poorer performance on standardized achievement tests, compared with children who are not exposed to aircraft noise. The RANCH study (Road traffic and Aircraft Noise and children's Cognition & Health) is a large-scale cross-sectional study of 2,844 children aged 9–10 years from 89 schools around London Heathrow, Amsterdam Schiphol, and Madrid Barajas airports. It found a causal link between

[15] Clark C., *Aircraft Noise Effects on Health: Report Prepared for the UK Airport Commission. Report Number 150427*. London: Queen Mary University of London, (2015). Exhibit 30.

aircraft noise and poorer reading comprehension and poorer recognition memory.[16] These associations were not explained by air pollution.[17] Children's aircraft noise exposure at school and that at home are often highly correlated.[18] In the RANCH study, night-time aircraft noise at the child's home was also associated with impaired reading comprehension and recognition memory.[19] See Safety/Health response #4

ii. Chronic aircraft noise exposure is linked to low birth weight.

Health economists from Lehigh University, Lafayette College and the University of Colorado, Denver, pinpointed a causal link between aircraft noise and low birth weight.[20] This study focused on the effects of aircraft noise on babies' health at birth, specifically low birth weight born to mothers living near Newark Liberty International Airport after implementing NextGen flight procedures at the airport. The study concluded that low birth weight was tied to implementing

NextGen flight procedures. The flight procedures over Pittsfield Township are also NextGen flight procedures. One economist, Muzhe Yang of Lehigh University stated that "[o]ur findings have important policy implications regarding the trade-off between flight pattern optimization and human health. This is especially important given the long-term negative impact of low birth weight on a range of later-life outcomes such as lifetime earnings, educational achievement, and long-term health."[21] See Safety/Health response #4

d. Aircraft noise causes poorer mental health.

Studies have also been conducted to show the link between aircraft noise exposure and poorer well-being, lower quality of life, and psychological ill health. In a 2020 study, researchers determined that noise annoyance, particularly from aircraft, is associated with depression, anxiety, and sleep disturbance over a five-year period.[22] The research concluded that over the five-year period, general noise annoyance remained stable and that "daytime noise annoyance predicted new onset of depressive, anxiety symptoms (also nighttime annoyance) and sleep disturbance." These results "indicate the need to provide regulatory measures in affected areas to prevent mental health problems." These results confirmed the findings in a 2010

study of 2,300 residents near Frankfurt airport that annoyance was associated with self-reported lower quality of life.[23]

See Noise response #1 and
Safety/Health response #11

e. Aircraft Noise Has Increased the Community's Annoyance with Environmental Noise.

i. International Organization for Standardization creates standards to address elevated levels of community annoyance from aircraft noise.

Community annoyance refers to evaluating the disturbing aspects or nuisance of a noise situation by a "community" or group of residents, combined in a single outcome. To help with comparisons and data pooling, members of the International Commission on Biological Effects of Noise proposed a standardized annoyance question[24] that was adopted by International Organization for Standardization ("ISO") as TS 15666.[25] The percentage of highly annoyed respondents is considered the main indicator of community annoyance. Using a common question has allowed researchers to compare studies from around the globe.

[23] Schreckenberg D, Meis M, Kahl C, Peschel C, Eikmann T., *Aircraft noise and quality of life around Frankfurt Airport,* 7 Int. J. Environ. Res. Public Health 3382 (2010). Exhibit 38.
[24] Fields JM, De Jong RG, Gjestland T, Flindell IH, Job RF, Kurra S, et al., *Standardized general-purpose noise reaction questions for community noise surveys: Research and a recommendation*, 242 J. Sound Vibr. 641 (2001). Exhibit 39.
[25] IS Organization, *ISO TS 15666: Acoustics- Assessment of Noise Annoyance by Means of Social and Socio-Acoustic Surveys* (2003). Exhibit 40.

Because of this step forward, in 2016, the ISO published a new standard to assess community annoyance because of environmental noise, such as aircraft noise. ISO 1996-1:2016, *Acoustics – Description, measurement, and assessment of environmental noise*, Exhibit 41, helps policymakers in predicting the potential annoyance response of a community to long-term exposure to several types of environmental noises, including aircraft noise. Although the U.S. has approved ISO 1996-1:2016 as being "state of the art," and ready for use in the United States, FAA has refused to use it in assessing aircraft noise in communities. Use of this tool in developing flight procedures would allow FAA to better evaluate and manage aircraft noise exposure. See pp. 35-40, *infra* for complete discussion of ISO 1996-1:2016.

See Noise response #1, #4, and #5.

ii. Community annoyance from aircraft noise is increasing.

In 2017, the United Kingdom Civil Aviation Authority undertook a survey of "noise attitudes." The study examined evidence on attitudes to aircraft noise around airports in England, including the effects of aircraft noise on annoyance, well-being, and health. It found that the level of noise exposure that leads to significant community annoyance has fallen from 57 dB L_{Aeq} (in an earlier survey) to 54 dB L_{Aeq}.

In 2016, the long-term German study entitled, "Noise-Related Annoyance, cognition, and Health" (NORAH) concluded there has been a change in annoyance responses: people are now more highly annoyed by aircraft noise than 30 years ago.[26] The NORAH study examined noise responses following the opening of a new runway, and implementation of a night curfew. The NORAH study mentions that several attempts are being made at trying to explain the variance within the annoyance response, using modelling to calculate the weight of non-acoustic factors. The NORAH study concluded that more people were "highly annoyed" when they experienced an increase in aircraft noise and that annoyance remains through the years. People do not habituate to aircraft noise.

Annoyance with aircraft noise amongst the affected population is increasing, not decreasing. The authors of 2011 report looked at datasets from separate airports in various parts of the world, including the U.S. from 1967 until 2005.[27] The results suggested there has been a significant increase in annoyance over the years. Instead of a gradual increase, the study showed increased levels of annoyance from

---

[26] Schreckenberg, D. et al. *Effects of aircraft noise on annoyance and sleep disturbances before and after the expansion of Frankfurt Airport – results of the NORAH Study WP1 'Annoyance and Quality of Life',* Internoise Congress, Hamburg (2016). Exhibit 42.
[27] Janssen, S. et al., *Trends in aircraft noise annoyance: the role of study and sample characteristics,* 129 J. Acoust. Soc. Am. 1953 (2011). Exhibit 43.

1996 onward. This is despite FAA's self-congratulatory declarations that aircraft noise is decreasing.[28] See Noise response #1, #2, and #4.

iii. FAA's recent Neighborhood Environmental Survey underscores growing community annoyance with aircraft noise.

The method for representing the community response to noise is known as the "Schultz Curve," which is a dose-response curve developed in the 1970's. The noise thresholds used for current FAA noise policy are informed by the "Schultz Curve." While the "Schultz Curve" remains the accepted standard for describing transportation noise exposure-annoyance relationships, its original supporting scientific evidence and social survey data were based on information from the 1970s. The last in-depth review and revalidation of the Schultz Curve was conducted in 1992 by the Federal Interagency Committee on Noise ("FICON Report"). More recent analyses have shown that aviation noise results in annoyance levels higher than other modes of transportation. Recent international social surveys have also generally shown higher annoyance than predicted by the Schultz Curve. These analyses and survey data indicate that the Schultz Curve may not reflect the current U.S. public perception of aviation noise.

---

[28] "By one measure, it has been a success: over the last four decades, the number of people in the U.S. exposed to aviation noise has dropped substantially, even as the number of flights has soared." https://www.faa.gov/regulations_policies/policy_guidance/noise/ (last accessed December 23, 2020).

In 2015 and 2016, FAA conducted a nationwide survey to measure the relationship between aircraft noise exposure and annoyance in communities underneath flight paths. This survey captured the community response to a modern fleet of aircraft as they are being flown today and it used best practices in terms of noise analysis and data collection. This survey has been called the "Neighborhood Environmental Survey" (NES). See Exhibit

For the NES, FAA surveyed over 10,000 residents living near 20 representative airports via a mailed questionnaire. The questionnaire asked the recipients about various environmental concerns that bothered, disturbed, or annoyed them. Noise from aircraft was one of the thirteen environmental concerns that the survey covered. Since the aircraft noise question was one of 13 environmental concerns listed, the recipient did not know whether this was an airport community noise survey. This was the largest survey of this type undertaken at one time. The data from the survey was used to calculate the new "National Curve" to replace the "updated Schultz Curve" in use by the FAA and provides a contemporary picture of community response to aircraft noise exposure. A follow up phone survey was also offered to the 10,000 mail survey respondents, and just over 2,000 elected to participate. The phone survey provided additional insights on how the mail survey respondents felt about aircraft noise.

The results of the survey showed that the updated Schultz Curve, as used in the FICON Report, was antiquated, and no longer reflected the public's response to aircraft noise exposure. Comparison of the FICON Report prepared using the updated Schultz Curve and NES prepared using the National Curve showed the following percentage of population highly annoyed by exposure to transportation noise:

- At a noise exposure level of DNL 65 dB, the FICON Report indicated 12.3% of people were highly annoyed, compared to between 60.1% & 70.9% from the NES.

- At a noise exposure level of DNL 60 dB, the FICON Report indicated that 6.5% of people were highly annoyed, compared to between 43.8% & 53.7% from the NES.

- At a noise exposure level of DNL 55 dB, the FICON Report indicated that 3.3% of people were highly annoyed, compared to between 27.8% & 36.8% from the NES.

- At a noise exposure level of DNL 50 dB, the FICON Report indicated that 1.7% of people were highly annoyed, compared to between 15.4% & 23.4% from the NES.

Extrapolating from the FAA's current "thresholds of significance," one concludes that the new "threshold of significance" should be around DNL 45 dB.

See Noise response #1, #2, and #4

iv. WHO Environmental Noise Guidelines for European Region (October 2018) establish new, science-based thresholds of significance.

In October 2018, the World Health Organization (WHO) Regional Office for Europe published its Environmental Noise Guidelines for the European Region ("WHO Guidelines") Exhibit 44. Those Guidelines found that aviation noise was connected to higher incidence of ischemic heart disease, hypertension, "prevalence of 'highly annoyed'" population, and a delay in reading skills and oral comprehension in children. WHO Guidelines. WHO strongly recommended that average levels of noise produced by aircraft be reduced below 45 dB DNL, as aircraft noise above this level is associated with adverse health effects. WHO Guidelines, pp. xvii, 61.

WHO also strongly recommended that noise levels produced by aircraft be reduced during nighttime below 40 dB DNL, as aircraft noise above this level is associated with adverse effects on sleep. WHO strongly recommended that to reduce health effects policymakers implement "suitable measures to reduce noise exposure from aircraft in the population exposed to levels above the guideline values for average and night noise exposure." WHO Guidelines, pp. xvii, 61.

See Noise response #1, #2, #5, and #10.

2. MDOT and ARB must protect the surrounding community from aviation noise.

It is "the policy of the United States … that aviation facilities be constructed and operated to minimize current and projected noise impact on nearby communities." 49 U.S.C. § 47101(a)(2). Part of the FAA's mission, and therefore

MDOT's mission, is to ensure that the communities surrounding airports are not hurt by noise from aircraft at airports. This mission is expressed in 49 U.S.C. § 47101(c), which states that "[i]t is in the public interest to recognize the effects of airport capacity expansion projects on aircraft noise. Efforts to increase capacity through any means can have an impact on surrounding communities. Noncompatible land uses around airports must be reduced and efforts to mitigate noise must be given a high priority." Thus, if noncompatible land uses around airports cannot be reduced, then the capacity of nearby airports should not be increased or else the FAA and the airport sponsor would violate federal law. ARB and MDOT seem aware that increases in capacity at the airport will affect the noise levels in Pittsfield, because they studiously have avoided the topic. Noise impacts of the increase in jet operations at ARB have not been analyzed or account for in the SRDEA. See Noise response #1, #3

MDOT has the legal duty to protect residents and property owners from the deleterious effects of aircraft noise. Federal law establishes the absolute duty of the government to protect both people and property from aircraft noise. "[T]he Congress declares that it is the policy of the United States to promote an environment for all Americans free from noise that jeopardizes their health or welfare." 42 USC § 4901(b). MDOT's statutory duty to protect people and property on the ground from the deleterious effects of aircraft noise goes beyond its duty under NEPA to determine what it believes to be "significant" or "reportable" under FAA Order 1050.1F. Legally speaking, the MDOT cannot conclude that a proposed MDOT action purportedly not "reportable" under 1050.1F, § 14.5e or that purportedly does not have a "significant impact" under 1050.1F, § 14.3, is not subject to review and regulation under 42 USC § 4901(b), 49 U.S.C. § 40103(b)(2) and 49 U.S.C. § 44715(a)(1)(A). Those statutory obligations require that the lead agency address aircraft noise separate from its duties under NEPA because the lead agency's proposed action will create aircraft noise that will have a deleterious effect on the public health and welfare. See Noise response #1, #3, an #4.

3. ARB and MDOT incorrectly assume that extending the runway will not significantly increase the number of air operations, the fleet mix, or other growth-inducing effects of the Project.

When considering an airport project for federal funding, the FAA must evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project (40 C.F.R. § 1508.8(b)) and increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). The "growth-inducing effects of [an] airport project appear to be its *raison d'etre*." *California v. U.S. D.O.T.*, 260 F.Supp.2d at 978, citing *City of Davis, supra*, 521 F.2d at 675. Even though the Project is virtually defined by its growth-inducing impacts, ARB and MDOT have ignored this requirement completely – not only in the SRDEA, but in the public participation parts of the Project as well. There is substantial evidence to indicate that the Project will cause a significant increase in both night and jet operations.

See Noise response #2, #3, and #14

As indicated above, the runway need not be extended for most of ARB's "critical aircraft" to operate at the airport without weight restrictions. For example, it is clear that the "load restrictions" referenced in the SRDEA will apply to the higher category aircraft (jets in the C-I and C-II ARC categories) even with a 4,225-foot runway. Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, which discourages these aircraft from conducting operations at ARB. A Cessna Citation II (Category B-II), for example, requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and, most days, can operate at unrestricted weight from ARB's existing 3,505-foot runway. A Lear 35 (Category C-I), on the other hand, requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,225 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be substantially diminished. Therefore, the runway extension to 4,225 feet would operationally benefit the Category C-I Lear

35, but would provide little or no operational benefit to the Category B-II Citation jet, which the SRDEA claims is a "critical aircraft." Thus, with the runway extension ARB does not become any more or any less attractive to the operator of the Citation II, but becomes much more attractive to the operator of the Lear 35. This would cause an increase in usage of ARB by the Lear 35, but the same usage by the Citation II. This is not reflected in the SRDEA's noise analysis or in the Runway Justification Study, which relies on the FAA's Terminal Area Forecast.

The primary reason ARB is so keen on extending the runway is to facilitate the loading of additional passengers and baggage on high performance jet aircraft outside of what ARB considers to be its "critical aircraft." Also, the ability to carry more fuel may mean that, in certain cases, costly and time-consuming intermediate fuel stops will become unnecessary. If the runway is lengthened to 4,225 feet, it is reasonably foreseeable that ARB will become much more attractive to operators of higher performance jet aircraft, such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II), who could then operate at ARB instead of driving to and from Willow Run Airport, a mere 12.3 mile car trip, where there are ample facilities for large aircraft. In an earlier draft of the Runway Justification Study, MDOT indicated that it believed that jets currently based at YIP may move their operations to ARB if the runway is extended. These additional ARB-based jets are not included in the forecasts on which both the Runway Justification Study and the SRDEA's noise analysis is based.

See General response #5; Noise responses #1 & #2; and Technical responses #2, #7, #8, #9

4. The RDEA does not analyze the fact that night and jet operations will increase because of the Project.

It is reasonably foreseeable that the fleet mix at ARB will change in favor of a higher percentage of jet operations as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft currently account for a high percentage of ARB operations. B-II aircraft account for a low percentage of ARB operations. Because of the availability of a longer runway, it is therefore reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer haul business jets often occur in the evening hours due to the longer time duration of their trips. Since one of the stated "benefits" of the Project is to increase interstate commerce (SRDEA, Appendix N, p. 9), this is not merely an indirect, but also a direct effect, that the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions. Because there is a potential of an increase in the number of operations, it must be analyzed thoroughly.

The evidence is clear that the Project will cause an increase in both jet and night operations. It is also reasonably foreseeable that these added high-performance jet aircraft operations and night operations will come with significant noise and air quality impacts. Still, ARB and MDOT have not acknowledged, let alone analyzed, these reasonably foreseeable impacts caused by expansion of airport physical facilities and operational profile and, thus, the Project should not be approved for funding. See Noise response #3, #10, and #14

5. Increased jet aircraft and nighttime operations were not included in the noise modeling used by ARB and MDOT.

The SRDEA states it used FAA's Aviation Environmental Design Tool (AEDT) to model annual operations for the 2019 "base" or existing condition in the SRDEA, to develop 65, 70 and 75 DNL noise contours for the Project. SRDEA, Appendix L. The RDEA states that "the 65 DNL contour remains completely within ARB owned property or over commercial property not considered noise sensitive under all noise scenarios." SRDEA, Appendix L, p. 7. The SRDEA noise analysis assumes that both the time of day of the operations and the fleet mix remain constant. See SRDEA, Appendix L, pp. 3-5.

During the period modeled, jet operations accounted for about 2 percent of total operations at ARB, and nighttime operations accounted for 4.2 percent of total operations. https://aspm.faa.gov/tfms/sys/ Airport.asp. Because of the increase in the length of the runway the Project will facilitate an increased number of night operations, and a change in fleet mix that will include many more higher performance jet aircraft. DNL calculations depend on, among other things, forecast numbers of operations, operational fleet mix and times of operation (day versus night). SRDEA, Appendix L, pp. 2-3. However, ARB and MDOT have failed to model or assess future increased night operations and fleet mix changes resulting from the Project. See Noise response #1, #3, and #5

FAA Order 1050.1F requires an EA's noise analysis to include, among other things: (1) noise contours at the DNL 75 dB, DNL 70 dB and DNL 65 dB levels; (2) analysis within the proposed alternative DNL 65 dB contour to identify noise sensitive areas where noise will increase by DNL 1.5 dB ; and (3) analysis within the DNL 60-65 dB contours to identify noise sensitive areas where noise will increase by DNL 3dB, if DNL 1.5 dB increases as documented within the DNL 65 dB contour. FAA Order 1050.1F, Appendix A, p. A-62, & 14.4d. As the noise modeling failed to account for the foreseeable increases in nighttime and jet aircraft operations at ARB, the questions of whether the future DNL 65 dB contour will be increased, and to what extent, and whether increased noise levels within the DNL 65 dB contour would require designation of a DNL 60 dB contour remain unanswered. See Noise responses #1, #5, and #10

6. **Federal law and NEPA required that MDOT use ISO to calculate the noise impact of the runway extension in the community surrounding ARB.**

The NEPA regulations mandate that federal agencies "insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements." 40 C.F.R. § 1502.24.[29] In addition, the Data Quality Act (also called the Information Quality Act, Section 515 of the Consolidated Appropriations Act, 2001 (Pub. L. 106-554)) requires that agencies to use the best scientific methods in technical matters. ISO 1996-1:2016, entitled "Acoustics -- Description, measurement and assessment of environmental noise -- Part 1: Basic quantities and assessment procedures," which was published in March 2016, defines the basic qualities to be used for the description of noise in community environments and describes basic assessment procedures. ISO 1996-1:2016 predicts the potential annoyance response of a community to long-term exposure to noise based on characteristics of the community rather than based on the noise created. As a product of the International Organization for Standardization, ISO 1996-1:2016 represents the best science for assessing the impact of noise on affected communities. Therefore ISO 1996-1:2016 must be used to avoid a violation of NEPA and the Data Quality Act. See Noise responses #1, #5, and #10

7. The Levels used in NES and the WHO Guidelines Should Have Been Used.

[29] The courts have applied this standard to EAs as well as EISs. *See, e.g.*, *Idaho Sporting Congress v. Thomas*, 137 F.3d 1146, 1152 (9th Cir. 1988)

Both the FAA's "Neighborhood Environmental Study" and the World Health Organization's Guidelines, indicate that it is imperative that levels well below 65 DNL need to be examined for their impact on public health and safety. It is also imperative that this study be done now, not be in the future after the runway extension is built. Both the NES and Guidelines indicate that 45 DNL is a more appropriate threshold of significance than 60 DNL. Because MDOT fails to analyze to these levels, the SRDEA is inadequate and incomplete.

See Noise responses #1, #5, and #10

C. Air

1. Aircraft Emissions have caused health risks to people living under flight paths.

Besides the health risks of aircraft noise, substantial research has been performed on the health risks posed by air toxics and particulate matter emissions from airports. This includes a 2014 study that showed that concentrations of particulate matter, black carbon, and nitrogen oxides (NO2) are elevated fourfold within six miles downwind of the airport and twofold within 10 miles from airport emissions. Hudda et al. *Emissions from an International Airport Increase Particle Number Concentrations 4-fold at 10 km Downwind*, Environmental Science & Technology, 2014 48(12), pp.6628-6635. Exhibit 45. In that study, researchers from University of Southern California's Keck School of Medicine conducted the analysis in a region near Los Angeles International Airport over 29 days, usually during times of onshore westerly winds in the late morning and afternoon. But measurements also were taken in early mornings and late nights when air traffic and onshore winds are lower. They found chemical concentrations to be up to five times higher than background pollution levels of an area within nine square miles of the airport. Within two miles east of the airport, levels of dangerous particulates were 10 times higher than in areas not affected by the airport's emissions. As a result, residents living downwind and to the east of the airport could inhale hazardous levels of nitrogen oxides and fine particulates that could contribute to inflammation, blocked arteries, asthma, heart conditions and other health issues.

The results from LAX were confirmed in a 2016 study at Boston's Logan Airport[30] where it was determined that aviation activities affected ambient ultrafine particle number concentrations ("PNC"). The study concluded there is a correlation between aviation activity and concentrations of ultrafine particulate matter and NO2. Two years later, in 2018, the same research group found that ultrafine particles from aviation activity penetrate indoors:[31]

> Overall, our results indicate that aviation-related outdoor PNC infiltrate indoors and result in significantly higher indoor PNC. Our study provides

[30] N. Hudda et al., *Aviation-Related Impacts on Ultrafine Particle Number Concentrations Outside and Inside Residences near an Airport,* February 7, 2018, Environmental Science & Technology. Exhibit 46.

[31] N. Hudda et al., *Aviation-Related Impacts on Ultrafine Particle Number Concentrations Outside and Inside Residences near an Airport,* February 7, 2018, Environmental Science & Technology. Exhibit 46.

> compelling evidence for the impact of aviation-related emissions on residential exposures.

These findings were confirmed in 2020.[32] Likewise, in 2020, it was reported that pregnant mothers exposed to aircraft emissions resulted in preterm births.[33] This analysis evaluated whether ultrafine particulate matter (UFPs) from jet aircraft emissions are associated with increased rates of preterm birth (PTB) among pregnant mothers living downwind of Los Angeles International Airport (LAX). The result was that *in utero* exposure to aircraft-origin ultrafine particles was positively associated with preterm births. This led the researchers to conclude that:

> emissions from aircraft play an etiologic role in PTBs [pre-term births], independent of noise and traffic-related air pollution exposures. These findings are of public health concern because UFP exposures downwind of airfields are common and may affect large, densely populated residential areas.

One of the perceived difficulties in assessing aircraft emissions was put to rest in a February 21, 2021, report that distinguished between roadway particle pollution and aircraft particle pollution.[34] The Mobile ObserVations of Ultrafine Particles (UFP) study found that key differences existed in the particle size distribution and

---

[33] S. Wing et al., *Preterm Birth among Infants Exposed to In Utero Ultrafine Particles from Aircraft Emissions*, April 2, 2020, Environmental Health Perspective. Exhibit 48.
[34] E. Austin et al., *Distinct Ultrafine Particle Profiles Associated with Aircraft and Roadway Traffic*, February 21, 2021, Environmental Science & Technology/. Exhibit 49.

the black carbon concentration for roadway and aircraft features. These differences can help distinguish between the spatial impact of roadway traffic and aircraft UFP emissions using a combination of mobile tracking and standard statistical methods.

Particulate pollution is not the only concern. In 2008 the Airport Cooperative Research Program produced an analysis entitled "Aircraft and Airport-Related Hazardous Air Pollutants: Research Needs and Analysis," which was funded through the FAA. That analysis provides direction on how airports should be able to address the requests from states and "communities surrounding airports to analyze the health impacts of aircraft and other airport-related sources of air toxics, also known as hazardous air pollutants (HAPs), in National Environmental Policy Act (NEPA) and state-level documents." Indeed, the health effects of emissions of air toxics from airports on the surrounding communities has been studied regarding large California airports under state law. The conclusion is inescapable: the HAPs emitted by airports create health risks to the surrounding communities and any project that increases the emission of HAPs into the air should be analyzed.

At the very least, the MDOT should require a Hazardous Air Pollutants inventory under FAA's guideline set out in *Guidance for Quantifying Speciated Organic Gas Emissions from Airport Sources*, (Ver. 1, September 2, 2009) ("HAP

Guidance") Exhibit 50.[35] According to the FAA, the HAP Guidance "provides an approach to, and technical guidance for, preparing speciated OG/HAP emission inventories in support of environmental documents prepared by, or on behalf of, the FAA under the National Environmental Policy Act (NEPA)." With the establishment of HAP Inventory, there would be, at least, a baseline for future health risk assessments showing the deleterious effect that airport emissions have on the surrounding communities. See Safety/Health response #17 and Air Quality response #4

While establishing a HAP Inventory is a step in the right direction, what is needed is a study that quantifies the substantial health risks that HAP emissions resulting from the SoCal Metroplex project present to surrounding communities. Toward that end, a more significant finding is the May 8, 2009, article *Between-airport heterogeneity in air toxics emissions associated with individual cancer risk thresholds and population risks*, by Ying Zhou and Jonathan I. Levy. Exhibit 51. In that article, the authors conclude:

> Using state-of-the-art four-dimensional emissions characterization and atmospheric dispersion modeling, we demonstrated that both the emission rate contributing to a 10^{-6} maximum individual risk and the total population exposure within 50 km of the airport per unit emissions vary substantially across airports *but can be predicted with reasonable precision using easy to*

[35] In addition, the FAA and the EPA has published the *Recommended Best Practice for Quantifying Speciated Organic Gas Emissions from Aircraft Equipped with Turbofan, Turbojet, and Turboprop Engines* which details joint efforts between the FAA and the EPA to update OG/HAP speciation profile data from these types of aircraft.

> *obtain variables, such as distance from the airport, total population, and mixing height.* These results provide a method to quickly but reasonably determine the likelihood of public health impacts of concern for airport modifications or expansions.

Zhou Levy Article, p.10 (emphasis added). In developing their conclusions about air toxics at airports, Zhou and Levy used the AERMOD high resolution atmospheric dispersion model, which is an FAA–approved model.

Because of the increase in aircraft flying at low altitudes directly over Pittsfield Township, ultrafine particulate matter and various contaminants have increased in the air above Pittsfield Township. Consequently, the citizens of Pittsfield Township are breathing in more particulate matter and inhaling contaminants that can lead to serious health effects. See Safety/Health response #4

The significant harms to human health of poor ambient air quality are well known. Extensive correlations have been demonstrated in diverse illnesses, affecting all segments of the population. Air quality related illnesses include breast cancer, brain tumors, asthma and non-smoking COPD, heart attacks, poor cognition, Sudden Infant Death Syndrome (SIDS), neonatal ICU admissions and preterm delivery. Recent data linking Traffic Related Air Pollution (TRAP) to Pregnancy related complications such as preeclampsia and gestational hypertension, is alarming given the maternal mortality crisis occurring nationwide. A well-designed study documented airport delays and taxiing time to an increased incidence of hospitalizations for asthma and heart attacks. Data is now emerging regarding the specific risk of UFPs. UFPs cause unique risk to health because their small size allows passage across tissue barriers, including the difficult to permeate blood-brain barrier. Recent NIH studies have shown UFP exposure related brain tumors, childhood cancers, asthma, heart attacks, mental health issues, including teen ER visits for anxiety and suicidal ideation, and various pregnancy complications, specifically preterm birth. Babies and children may be susceptible because they accumulate UFPs at relative concentrations higher than adults. Recent COVID-19 related public health trends, specifically decreased asthma admissions and preterm birth and increased COVID-19 mortality for residents in areas of poor air quality, are tangible examples of the real-time consequences of air quality. One recent study showed an increase by only 1 μg/m3 of PM2.5 is associated with an 8% increase in the COVID-19 death rate. It is imperative we quantify the emissions pollutant volume and dispersal patterns regarding public health and environmental justice.

See Safety/Health response #4 and Air Quality response #1

D. Water

1. SRDEA fails to adequately consider water issues.

The SRDEA consistently understates the significance of water resources. SRDEA, pp. 3-32 – 3-45. The principal use of the grounds where the airport is located is for the collection and pumping of water for the City of Ann Arbor.

However, water quality must be taken much more seriously than the SRDEA takes it. As FAA Order 1050.1F points out, the significance threshold is breached when the action would “contaminate an aquifer used for public water supply such that public health **may** be adversely affected.” FAA Order 1050.1F, p. 4-12. The 1050.1F Desk Reference elaborates that “[i]f there is the potential for contamination of an aquifer designated as an EPA-designated sole source aquifer for the area, the FAA must consult with the EPA regional office as required by Section 1424(e) of the SDWA.” That is the case here, but there is no indication in the SRDEA that MDOT consulted with EPA. See Water Resources/Water Quality response #5

The Airport is located on a porous sand/gravel formation that yields a large amount of water for pumping. The land where the airport is located was originally acquired by the City of Ann Arbor for water rights in 1921. Currently, about 25% of Ann Arbor’s water supply come from the three wells on Airport property. The paving that the Project will require increases not only the impervious area on top of the aquifer, but also increases the risk of contamination, particularly from PFAS contamination that may exist in the soil from firefighting foam that may have been used at ARB for firefighting and for training. This, in turn, reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer vital to the City of Ann Arbor. See General response #6, Water Resources/Water Quality response #1

So critical is drinking water from the airport wells to the city that de-icing is prohibited on the airport. Due to the 'unmaintained nature' of the airport vegetation, it is acting as a buffer around the wellheads," the water faces many potential threats from a lengthened runway. Those threats become more critical because of the potential for lead to contaminate Ann Arbor's water supply. Most of the fuel used at ARB is consumed by piston-driven aircraft, which mostly use leaded AvGas. Any risk to the aquifer underlying the airport could pose a threat of lead contamination. With Ann Arbor's other water resources affected by dioxane risks caused by the "Gelman spill," the Airport well-field has taken on a much more significant role. The SRDEA, however, gives this issue only passing mention. See SRDEA, pp. 3-41 – 3-44. Notably absent from their coordination efforts is the EPA or its Regional Office regarding water resource issues.

See Water Quality/Water Resources response #1 and #7

Because the wells on ARB property is a principal source of Ann Arbor's water supply, the Washtenaw County Water Resources Commissioner raised serious issues about the Project in the past. In response to the draft 2010 EA, the Washtenaw County Water Resources Commissioner pointed out:

> It is noted in the [draft EA] that: "The amount of impervious surface on site would increase slightly due to the extension of the runway and taxiway from the existing 7 percent of the 837 acres to 7.4 percent." This slight increase noted equates to an additional 3.348 acres or 145,839 square feet. This increase in impervious surface is considered by this office to be significant

> and not slight particularly knowing that the additional runoff from this area will discharge to the Wood Outlet Drain.

Exhibit 52, p.2. This, coupled the City owning and operating four water wells on ARB's property, caused deep concern with the County.

This issue has become even more important since the draft EA was published back in 2010. In May 2012, for example, it was reported that the water table in the Ann Arbor area, has risen substantially. As pointed out in the Ann Arbor Chronicle, "[t]he only hard data that the city has collected on the water table is at the municipal airport, and there the water table measures between 2-7 feet below the surface now, compared to 15 feet below the surface 50 years ago." Exhibit 53. This is not an insubstantial problem. With the water table at the airport now being 2-7 feet below the ground surface instead of 15 feet, when the drinking water wells were first dug, the groundwater is even more vulnerable to contamination because there is much less soil for any surface pollution to filter through or attach to soil particles before it reaches the water table. This dramatic change in the water table may also alter groundwater data from the past. That is, the rise in the water table may have altered the direction of groundwater flow, or there may now be some barrier blocking the traditional pathway for the water to flow, which would cause Ann Arbor's principal drinking water supply to be contaminated.

See Water Resources/Water Quality response #1

In the past the Washtenaw County Water Resources Commissioner raised additional significant concerns that have yet to be addressed by either ARB or MDOT.

> 3. It is indicated that the preferred alternative does not impact the stream that is existing on the site. [Draft EA, p.4-18]. Using GIS measurements it appears that the stream is less than 1,000 linear feet from the existing runway. The runway extension would bring this infrastructure within 50 linear feet or less of the stream. In addition to this the grading limits shown in Appendix D-7 clearly extend into and beyond the location of the stream. Based on this information *it is not understood how it has been concluded that there are no impacts to the stream*.
>
> 4. It is indicated that the preferred alternative does not impact the floodplain for the stream that is existing on the site. It is indicated that proposed grading for the expansion would not occur within the designated floodplain boundary. [Draft EA, p.4-24]. Based on the floodplain boundary shown on FEMA Community-Panel Number: 260623 0010 C these statements are incorrect. Not only do the grading limits indicated for the preferred alternative extend into the floodplain boundary but the runway extension itself will extend into this floodplain boundary. Based on this information it is *not understood how it has been concluded that there are no impacts to the floodplain.*
>
> ….
>
> 6. It is noted in the report that: "Implementation of appropriate best management practices (BMPs) would continue to control the rate of stormwater runoff and maintain water quality standards." [Draft EA, p.4-18]. It is unknown by this office as to what the control rate of stormwater is currently being implemented or whether this rate meets county standards. *The additional volume created by this increase in imperviousness is not spoken to at all by the report. The type or locations of the appropriate BMPs indicated are not identified.*

Exhibit 52, pp.1-2 (emphasis added). Pittsfield Township has the same concerns about how water resources will be managed by ARB should this Project move forward. If there has been a change to the Project that addresses these concerns, they should have been addressed in the SRDEA. As such, these issues have not been sufficiently addressed by the SRDEA.

MDOT and ARB have a responsibility under the law to ensure the safety of the water in Ann Arbor's wells. Further, although Pittsfield does not receive its drinking water from these wells, water from the same aquifer filling these wells is the source of water for many Pittsfield Township waterways, including the several ponds in the Stonebridge Community. Thus, beyond ensuring applicant Ann Arbor's compliance with the law, Pittsfield has a vested interest in ensuring the water in the aquifer be maintained to the highest possible quality level.

See Water Resources/Water Quality response #8

8. The EA Fails to Address Standards and Requirements Under the Michigan Safe Drinking Water Act

The Michigan Safe Drinking Water Act, Public Act 399, as amended, was enacted in 1976 and enables the Michigan Department of Environment, Great Lakes, and Energy (EGLE) to maintain direct control over the public drinking water program in the state.

Rule 325.10812, promulgated under the Michigan Safe Drinking Water Act, MCL 325.1001 *et seq*., provides that:

> R 325.10812 Location of wells; major sources of contamination. Rule 812. **Wells serving type I and type IIa public water supplies shall be located a minimum distance of 2,000 feet, and wells serving type IIb and type III public water supplies shall be located a minimum distance of 800 feet, from known major sources of contamination**, including large scale waste disposal sites, land application of sanitary wastewater or sludges, sanitary landfills, and chemical or waste chemical storage or disposal facilities. The department may require an increase or approve a decrease in the 2,000 foot distance for type I or type IIa public water supplies or the 800 foot distance for type IIb or type III public water supplies based on a study of hydrogeological conditions or other methods approved by the department for identifying the capture zone of a well. [Emphasis Added]

As acknowledged in the SRDEA, there are several water wells on ARB property. SRDEA, 3-42; Figure 3.9. Further, the ARB property is within a wellhead protection area, which represent the land surface area that contributes ground water to wells serving public water supply systems throughout Michigan. EA, 3-42; Figure 3.10. Specifically, the Steere Farm wells on ARB property provide a substantial portion of the public water supply to the surrounding community.

While the SRDEA sets forth certain actions and Best Management Practices ("BMPs") that "should be considered" because ARB is within a wellhead protection area, the SRDEA fails to address or analyze compliance with the minimum well isolation distances provided for under the Michigan Safe Drinking Water Act and the rules promulgated by the EGLE, nor does it identify the distances from the Project Area to the various wells located on ARB property.

See Water Resources/Water Quality response #9

Further, the EA's failure to address or analyze the requirements under the Michigan Safe Drinking Water Act leaves the public unable to fully assess whether the Project is subject to challenge under the Michigan Environmental Protection Act (MEPA), Part 17 of NREPA, MCL 324.1701-.1706. MEPA authorizes any person to bring an action "for the protection of the air, water, and other natural resources and the public trust in these resources from pollution, impairment, or destruction." MCL 324.1701(1), and prohibits conduct that "has polluted, impaired, or destroyed or is likely to pollute, impair, or destroy the air, water, or other natural resources or the public trust in these resources. MCL 324.1703(1); MSA 13A.1703(1)." *City of Jackson v. Thompson-McCully Co., L.L.C.*, 239 Mich. App. 482, 487-88, 608 N.W.2d 531, 535 (2000). The SRDEA fails to address MEPA, nor does it provide sufficient information to evaluate the applicability of potential action under MEPA, and consequently additional analysis related to compliance with the Michigan Safe Drinking Water Act and MEPA is required.

The Project should not be approved by MDOT until these requirements regarding water quality have been complied with fully.

See Water Resources/Water Quality response #9

VI. MDOT has not given the communities' interests "fair consideration" as required under federal law.

i.

The aviation statutes of the United States make it incumbent on MDOT to give the interests of the surrounding communities fair consideration. *See* 49 U.S.C. § 47106(b)(2). That statute requires that before any federal funding, including funds from the SBGP, of an airport development project takes place, "the interests of the community in or near which the project may be located have been given fair consideration." 49 U.S.C. § 47106(b)(2). Thus, before the Project moves forward, MDOT and FAA must ensure that Pittsfield Township's interests have been given fair consideration. See General response #2

A. The Expansion at Ann Arbor Municipal Airport Does Not Comply with Planning in the Surrounding Communities.

MDOT has a duty under the law and by contract to ensure that federal funds are used properly for airport development projects. It is imperative that the concerns and issues of the surrounding communities are considered *prior* to approval of a project. This policy is reflected not only in the statutes that the FAA (and MDOT, through its SBGP Contract) is bound to uphold, but in its regulations and guidance documents it has issued. One place this policy is shown is in the assurances that airport sponsors, owners and operators are bound to follow upon accepting federal funds for airport development. Grant assurances 6 and 7 state:

6. Consistency with Local Plans. The project is reasonably consistent

with plans (existing at the time of submission of this application) of public agencies that are authorized by the State in which the project is located to plan for the development of the area surrounding the airport.

7. Consideration of Local Interest. It has given fair consideration to the interest of communities in or near where the project may be located.

FAA Airport Sponsor Grant Assurances, Exhibit 54. ARB is bound by these assurances and must comply with them. Thus, approval of this project without the approval by Pittsfield Township would violate ARB's grant assurances.

See General response #2 and #15

B. ARB's and the City of Ann Arbor's Goals Are Different from Pittsfield's Goals.

While Pittsfield Township recognizes the "operational needs" presented in the SRDEA, it is less sympathetic with growth-inducing aspects of the project which would subject both the government of Pittsfield and the people of Pittsfield to untold potential future damage. This damage would come in the form of both safety risks and in economic loss because of repeated flights of low flying, heavy jet aircraft. Pittsfield and its residents would have no choice but to seek recovery in the event of a tragic accident or inverse condemnation class action proceedings, from the City potentially leaving Pittsfield victims without an effective remedy at law.

See Noise response #1 and #3, Safety response #2, and Financial/Economic response #1, #2, and #4

1. The Project would increase safety concerns of low-flying aircraft near surrounding densely populated communities

Petitioners would be subjected to a perfect storm of potential risks from low-flying aircraft in heavily populated neighborhoods also occupied by wildlife, including many Canada geese, during much of the year. *See* Exhibit 55 for map of ponds surrounding the airport that support Canada Geese. This is confirmed by a study conducted by MDOT and Ann Arbor's own airport architects (URS Corporation), which was excluded from the draft EA, and visualized on a projection of what the approach to an expanded Runway 6 would look like relative to the close proximity to area homes, which was corrected for accuracy. Exhibit 56.
The safety of having an airport so close to a densely populated area is not an unfounded fear. In June 2009, a small single-engine plane attempting to land at ARB instead made an emergency landing 1,200 yards short of Runway 6/24 on a Stonebridge Golf Club fairway in Pittsfield after its engine died at low altitude on final approach. Exhibit 57. The pilot said if there had been people on the fairway, he would have "crashed into the trees," which would have been fatal for him and his grandson, whom he was instructing. *Id*. In Fall 2022, a single-engine plane was forced to make an emergency landing in the ARB-owned agricultural field to the west of the airport after losing its engine on take-off. While that resulted in no

damage or injury, with an expanded runway that aircraft may have had nowhere to "ditch" other than in the heavily populated Stonebridge neighborhood across from the agricultural field. It is not insignificant that between 1973 and 2001 nine people died from accidents flying in the Ann Arbor Airport traffic pattern within three miles of the airport. Exhibit 58.

With Runway 6/24 extended 950 feet farther to the southwest and even closer to hundreds of homes, as proposed, and planes still lower on approach – and planes heavier, larger, carrying greater payloads, and more people – this poses a risk too grave to bring to a heavily populated community as well as to the users of ARB.

See Noise response #1; Wildlife response #1; and Safety/Health response #1, #2, #3, #5, & #6

9. Because of the Project ARB will attract more and heavier aircraft, which will increase the safety risk to the surrounding community as well lower their property values.

Extending Runway 6/24 by 950 feet will attract more and heavier jets (as well as larger multi-engine turboprop aircraft) while bringing them closer to heavily populated residential areas. ARB estimates that jets would be within 600 yards and at altitudes of 93 feet above rooftops of homes, or lower, on a regular basis. Aircraft landing on Runway 6 would pass Lohr Road below 90 feet, which is the site of a non-motorized bike path, the Lohr-Textile Greenway Project. Thus, low-flying, heavy jets would land just feet over people traversing this non-motorized trail.

This is especially dangerous with heavier aircraft because, in the event of any common multi-engine aircraft mishaps – such as an engine failure on takeoff, a bird strike on takeoff, climb out, or approach, or similar incident – with aircraft in very close proximity to homes, the risk could be grave – a perfect storm of environmental or human risk. For example, a twin- engine jet losing one of its engines would lose 80 percent of its climb performance. At low altitudes that could be tragic. Likewise, losing an engine in a light twin-engine aircraft would be catastrophic since the aircraft could not continue to climb on one engine in takeoff configuration. Neither could it turn back toward the airport at low altitude in takeoff configuration.

Such impacts and safety implications on political jurisdictions where airports are located and where the airport decision-making bodies are devoid of local citizens and local governments must be investigated carefully and thoroughly by the governmental entities empowered to protect the safety of all concerned. MDOT must protect the health and well-being of the people on the ground as well as those in the air from the inherent risks of aviation.

See Noise response #1 & #3, Safety/Health response #6, and Financial/Economic response #2

10. Expanding the Runway Will Result in an Increase in Violations of Pittsfield Township's Ordinances and Planning Procedures

a. Noise Ordinance

Pittsfield Township, within which ARB is located, has a long-standing noise ordinance making it unlawful for "any person to create, assist in creating, permit, continue, or permit the continuance of any unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township." Pittsfield Township has a duty to protect its citizens' health, safety, and property from "unreasonably loud, disturbing, unusual or unnecessary noise." Exhibit 6.

How the lengthening of the runway will affect the enforcement of this ordinance has not been examined, as required by NEPA, NEPA Regulations and FAA Order 1050.1F. If the ARB runway were expanded to the west, as proposed, and the noise impacts on Pittsfield residents were to change, this ordinance would face demands from citizens for more strenuous enforcement. Therefore, all aircraft flying in and out of ARB are subject to Pittsfield's noise ordinance and fines can be levied on the aircraft owners for operating their aircraft if they create an "unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township."

Justice Rehnquist, in the landmark case *City of Burbank v. Lockheed Air Terminal Inc.*, 411 U.S. 624 (1973) stated that the legislative history of the 1968 noise control amendment to the Federal Aviation Act, and the subsequent 1972 Noise Control Act, provided for local land use planning to control the noise impacts on communities surrounding airports. *Burbank*, 411 U.S. at 643. Justice Rehnquist further noted that the House Committee on Interstate and Foreign Commerce specifically advocated the cooperation of state and local governments in achieving noise control. *Id.* Justice Rehnquist concluded from the legislative history that Congress intended only that the FAA regulate the "source" of noise, specifically the "mechanical and structural aspects of jet and turbine aircraft design." *Id.,* at 650. The statute did not, however, limit the states and local authorities from "enacting every type of measure, which might have the effect of reducing aircraft noise . . ." *Id.,* at 650-651. Justice Rehnquist, thus, suggests that so long as local or state governments do not regulate aircraft noise emissions directly, for example by requiring aircraft to meet certain noise standards or requiring certain technical modifications to jet engine design, they may regulate noise for the common benefit.

Therefore, all aircraft flying in and out of ARB are subject to Pittsfield's noise ordinance and fines can be levied on the aircraft owners for operating their aircraft such that they create an "unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township."

See Noise response #13

b. Violation of Agreements between the City of Ann Arbor and Pittsfield Township.

ARB and Pittsfield Township have a long and contentious history. In 1979 Pittsfield Township and the City of Ann Arbor, the owner of ARB, reached an agreement intended to resolve issues at the Airport. Exhibit 7. In 2009, a new agreement was reached that incorporated the 1979 Agreement and sought to instill a sense of cooperation between the City of Ann Arbor and Pittsfield Township on issues regarding the Airport. Exhibit 8. The 2009 Agreement is automatically renewed, unless one party opts out.

Pittsfield Township's position is that extending the runway at ARB violates the 2009 Agreement, if not to the letter of the agreement, at least to the spirit of the agreement. The 2009 Agreement was drafted to foster cooperation between the City of Ann Arbor and Pittsfield Township on issues related to ARB. However, ARB's insistence on extending the runway over the strong opposition of Pittsfield Township is not being "cooperative." The runway extension violates the Agreement between the City of Ann Arbor and Pittsfield Township.

See General response #29

11. Runway expansion could cause Pittsfield Township to lose millions of dollars from reduced taxes.

There is extensive research to suggest an extension of the runway could cause severe economic losses to several communities surrounding the airport, including Pittsfield Township, in reduced real estate values and, reduced property and school taxes based on assessed property values. This reduction in home values is attributable to aircraft noise and emissions. How and to what extent the noise and emissions created by the Project will damage property values is not addressed in the SRDEA. Extensive research based on other communities in which airport runways have been extended – Atlanta, Reno-Tahoe, Chicago O'Hare, the Greensboro-High Point-Winston Salem metroplex, 23 cities in Canada, among others – show property values decline as runways are expanded. The most respected such study, *The Announcement Effect of an Airport Expansion on Housing Prices*, G.D. Jud & D.T. Winker, (2006), JOURNAL OF REAL ESTATE FINANCE AND ECONOMICS, 33, 2, 91-103, Exhibit 59, suggests house prices decline by about 9.2 percent within a 2.5-mile band of the airport, and, beyond that, in the next 1.5-mile band, prices decline another percent once an announcement – without extraneous influences – was made.

The lengthy hold up of the proposed ARB expansion has represented an extraneous influence since the initial announcement in 2007, but that if approved, these effects would occur at ARB. To further support this claim, a literature search could find no published, peer-reviewed research study where residential real estate values continued to rise in areas immediately surrounding an airport after runways were expanded. A decrease in property values in the areas surrounding ARB would have important consequences for the governmental bodies that benefit from property tax collections. In the corridors referenced in the Jud & Winker study noted above, there are:

- 6,239 Pittsfield Township parcels of land within the 2.5-mile area surrounding the airport; and
- 4,168 parcels within the 2.5-mile to 4-mile area.

These parcels will be subjected to a decline in real estate values of 9.2 percent and 5.7 percent, respectively due to the expanded runway. Using those facts, the following is the estimated value of what the potential **annual** losses in property tax revenue would be for various governmental bodies based on their tax collections in the year following the extension of the runway:

- $1.5 million less for the Ann Arbor School District;
- $1.4 million less for the Saline School District;
- $850,000 less for Pittsfield Charter Township; and,
- $810,000 less for Washtenaw County.

This estimate is only for property in Pittsfield Township. These numbers understate the decline in tax revenues, because they do not consider the potential effects of property in Lodi Township, the City of Saline, (both of which could affect the Saline School District's revenues), or property in the City of Ann Arbor. Thus, governmental bodies could stand to lose millions of dollars in operating funds annually from a runway expansion project that has yet to show any real economic benefit. See Financial/Economic response #2

12. MDOT must consider the interests and decisions of the surrounding communities

ii.

Both Pittsfield Township, where ARB is located, and neighboring Lodi Township have passed Resolutions opposing an expansion of the runway at ARB. Pittsfield passed two resolutions opposing the extension of the runway. The first was passed on March 24, 2009 (Exhibit 60), and the second was passed on April 12, 2017 (Exhibit 61). Lodi Township passed its resolution on May 12, 2009 (Exhibit 62). The Resolutions oppose the expansion because of the risks from Canada geese in areas surrounding the airport, low-flying aircraft on the approaching newly expanding runway, and that 99 percent of the based aircraft can operate at their full weight capacity on the existing runway. More important, though, the Resolutions seek to protect the health and property rights of their citizens. The Airport has ignored these Resolutions in the past and will do so again unless FAA or MDOT take them seriously when conducting an environmental assessment.

Ignoring the resolutions violates NEPA, NEPA Regulations and FAA Order 1050.1F, it is also a violation of ARB's federal grant assurances, exposing the City of Ann Arbor to litigation liability and potential loss of all federal funding for ARB. Going forward with the project without Pittsfield's sign-off is not being a good neighbor or keeping with the spirit of cooperation regarding Airport issues.

Given Pittsfield's and Lodi's resolutions of opposition, the expansion of the runway contradicts the will of those governing bodies. The expansion would benefit a minute number of airport users while placing at risk thousands of members of the Pittsfield and Lodi communities with added larger and heavier aircraft, flying much closer to their homes, at lower altitudes, in an area heavily populated by Canada geese, and in an increasingly dense residential area.

The consideration of the wishes of these local communities must be weighed, evaluated, and given "fair consideration" as required by the FAA's grant agreement with Ann Arbor. In the twelve years since the proposed expansion has been pending, for example, not even one study on the potential safety effects of the expansion on the residents of Pittsfield has been conducted. ARB and MDOT have consistently ignored the interests of communities surrounding ARB.

See Financial/Economic response #2, Wildlife response #1, Noise response #1, Safety/Health response #1 & #6, and General response #2 & #29

13. Any Environmental Assessment Must Properly Consider the Intensity of the Impacts on the Surrounding Community.

NEPA Regulation 40 C.F.R. § 1508.27 requires that the Project be placed in context with the surrounding society so the Project's impact on the affected region, the affected interests, and the locality can be rigorously evaluated. Any environmental document undertaken by MDOT must adequately address this aspect before the Project can be approved. This aspect of the environmental assessment process is often called "Intensity," and it requires consideration of:

> (1) Impacts that may be both beneficial and adverse. A significant effect may exist even if the Federal agency believes that the effect will be beneficial.
> (2) The degree to which the proposed action affects public health or safety.
> (4) How much the effects on the quality of the human environment are likely to be highly controversial.
> (5) How much the possible effects on the human environment are highly uncertain or involve unique or unknown risks.
> ….
> (10) Whether the action threatens a violation of Federal, State, or **local law** or requirements imposed for protecting the environment.

40 C.F.R. § 1508.27 (emphasis added). *See also* FAA Order 1050.1F, § 4-3.2, p.4-3.

The National Environmental Protection Act under which the SRDEA was prepared, and the due process clauses of the Fifth and Fourteenth Amendments to the United States Constitutions all provide legal protections to the residents living west of the Ann Arbor Municipal Airport. The citizens living in areas that surround the airport believe the airport expansion represents an arbitrary denial of their life, liberty, or property in violation of the Fifth and Fourteenth Amendments. These rights cannot be restricted except for a valid governmental purpose. *Bolling v.*

Sharpe, 347 U.S. 497 (1954). Critical is that any decision to move forward on the runway expansion must be made by a neutral decision-maker. Goldberg *v. Kelly*, 397 U.S. 254, 267 (1970). This is an important distinction because for four decades, MDOT has shown itself to be an advocate for expansion of the ARB primary runway, and not a neutral party. Typically, when a law or other act of government is challenged as a violation or potential violation of individual liberty under the due process clause, courts balance the importance of the governmental interest and the appropriateness of the government's method of implementation against the resulting infringement of individual rights. Where state authorities, such as MDOT, are involved, the United States Supreme Court has held that ". . . we cannot leave to the States the formulation of authoritative . . . remedies designed to protect people from infractions by the States of federally guaranteed rights." *Chapman v. California*, 386 U.S. 18, 22 (1967). Thus, MDOT may be forced to recuse itself from any decision in the Ann Arbor Municipal Airport expansion case, an expansion project which poses significant potential risks to citizens living in neighborhoods surrounding the airport.

This proposed project has a statistically small benefit, and yet would attract larger and heavier jet aircraft in closer proximity to homes in areas heavily populated with Canada geese, potentially jeopardizing residents if an accident occurs – accidents that the FAA contends are the third most frequent that occur in terms of incidents with hazardous wildlife in aviation. The risk to public safety may far outweigh any established benefit, which has not been substantiated. Added risks in terms of additional noise and night flights have not been established, but with arrival traffic traveling just 93 feet over rooftops on an expanded runway, it could have a controversial and negative impact on the human environment of citizens in Pittsfield Township, in violation of that township's noise ordinance and resolution, and in violation of federal law.

See Noise response #1 & #13, Wildlife response #1, Safety/Health response #1, and Safety/Health #2, #3, #5, & #6

VII. Conclusion

These comments detail why the SRDEA is inadequate and fails to meet the requirements of federal law, NEPA, the NEPA regulations, FAA Order 1050.1F as well as State and local laws. For the reasons stated above, the Project proposed by ARB should not be approved by either MDOT or the FAA because:

- The SRDEA does not state a valid Purpose and Need, rather, ARB attempts to justify its desire for an extended runway by creating a non-existent problem (or, at least, a problem that affects a picayune portion of the aircraft operating at ARB).

See Noise responses #1 & #3, Safety/Health responses #7 & #16, and General responses #3 & #14.

- The SRDEA does not establish by convincing evidence that the "critical aircraft" at ARB is a "B-II" type aircraft. In order to push its agenda, ARB has cherry-picked a year where operations of B-II aircraft exceeded 500 operations, but it ignores the fact that FAA regulations require there to be over 500 operations in 12 months preceding the environmental assessment. This fact obviates the "need" for an extended runway.

See Technical response #8 and #10

- The SRDEA does not address the fact that the proposed expansion brings potential risks to residents living near the airport by attracting larger and heavier jets, having aircraft take off 850 feet closer to population areas, and aircraft land just 93 feet over homes to the west of the airport.

See Noise response #1 & #3; Safety/Health response #6

- The SRDEA does not address the fact that the proposed expansion will have both noise and public safety impacts, violating a local Pittsfield Township noise ordinance. See Noise response #1, #4, and #13

- The SRDEA does not address the fact that both Pittsfield and Lodi Townships have passed resolutions oppose expanding the Ann Arbor Airport runway. This puts the proposed expansion at odds with 40 C.F.R. § 1508.27(2), (4), (5) and (10). See General response #29 and #33

- By carrying out the preferred alternative, ARB will be in violation of its FAA grant assurances which require it to consider the local interests of these communities, which there is no evidence presented in the SRDEA that it has done. See General response #5 and #18

In keeping with the above, if this proposed expansion is not rejected based on these above arguments, we ask that the following changes to the RDEA be required before the project moves forward:

(1) Compliance with Pittsfield Township's Noise Ordinance must be considered as a required part of the project.

(2) The SRDEA must address the fact that the preferred alternative is in direct opposition of Resolutions passed by both Pittsfield Township, the jurisdiction in which ARB is located, and Lodi Township, the adjacent jurisdiction. This puts the City of Ann Arbor at risk for litigation since it has signed grant agreements that state that the project must comply with local laws.

(3) The Alternative of using Willow Run Airport (YIP) to meet the RDEA's Purpose and Need must be fully considered as a "reasonable alternative" under NEPA and FAA Order 1050.1F.

(4) An updated noise study must be conducted that includes the effects of larger and heavier jet aircraft that an expanded runway will attract at night, and the health effects of such potential noise from positioning the runway 950 feet closer to the population center on citizens living near the airport.

(5) A Health Risk Assessment must be drafted to assess the public health risk as a result of the Project.

(6) The drinking water from wells on the airport property must be evaluated and provisions for further consultation with federal and state officials required (FAA Order 1050.1E (Pages A-76-76, 17.4a).

If you have any questions or comments, please feel free to call me at (626) 396-7300 or send me an email at staber@leechtishman.com.

Re: Comments by The Charter Township of Pittsfield on the Environmental Assessment for Ann Arbor Municipal Airport

Dear Ms. Lamrouex:

The following comments are submitted on behalf of The Charter Township of Pittsfield on the February 2010 Environmental Assessment for Ann Arbor Municipal Airport ("EA").

I. THE PROJECT'S STATED PURPOSE AND NEED IS UNSUPPORTED BY THE EVIDENCE.

An EA must include a discussion of the purpose and need for the proposed action which must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." [40 C.F.R. § 1502.13]. In addressing the Purpose and Need section of an EA, FAA Order 1050.1E provides that: "This discussion identifies the problem facing the proponent (that is, the need for an action), the purpose of the action (that is, the proposed solution to the problem), and the proposed timeframe for implementing the action." FAA Order 1050.1E, ¶ 405c. The EA accomplishes none of these goals.

A. The EA Supports Neither the Problem it Aims to Solve Nor its Purported Solution.

First, the EA defines the *purpose* of the Project[1] as "to provide facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport." [EA, p. 2-4]. The EA defines "critical aircraft" as "the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport," *Id.*, and states that a 2009 MDOT Airport User Survey "has confirmed that the critical aircraft classification for ARB is 'B-II Small Aircraft.'" *Id.*

To effectuate the stated purpose, the EA purports to support the construction of a runway extension from 3,505 feet to 4,300 feet. However, the extant evidence is clear that no "B-II Small Aircraft" require a 4,300 foot long runway. All B-II Small Aircraft are capable of operating on the existing 3,505 feet long runway without weight restriction. *See*, attached Williams Aviation Consultants Report [incorporated herein by reference]. In fact, the representative B-II Small Aircraft cited in the EA, the Beechcraft King Air 200, requires only 2,579 feet of runway to take-off fully loaded, and 2,845 feet to land. *See*, http://www.hawkerbeechcraft.com/beechcraft/ king_airb200gt/specifications.aspx. Thus, the statement that "[d]evelopment of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small Aircraft to operate at their optimum capabilities (without weight restrictions)" [p. 2-4], although true, is misleading. There is no need to extend Runway 6/24 to allow B-II aircraft to operate at ARB. They can operate on a 3,505 foot runway without weight restrictions. Therefore, the statement that interstate commerce would be negatively impacted by B-II Small weight restrictions does not state a valid need, and the purported purpose of "provid[ing] facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport" is an unnecessary solution to a nonexistent problem.

B. The EA Incorrectly Relies on ***Total*** Annual Operations to Support the Proposed Runway Extension.

The EA states, "[t]he critical aircraft, or grouping of aircraft are generally the largest, most demanding types that conduct at least 500 operations per year at the airport" [EA, p. 2-7], and concludes that the proper Airport Reference Code ("ARC") for ARB is "B-II Small", based on a total of "750 actual annual operations by B-II category critical aircraft from survey data year

---

[1] The proposed improvements described at page 2-1 of the EA are referred to herein as the "Project."

2007." [EA, p. 2-9]. However, the EA's use of "annual operations" differs markedly from the FAA criteria for selecting runway lengths and widths set forth in FAA Order 5090.3C:

> 3-4. AIRPORT DIMENSIONAL STANDARDS
>
> Airport dimensional standards (such as runway length and width, separation standards, surface gradients, etc.) should be selected which are appropriate for the critical aircraft that will make substantial use of the airport in the planning period. Substantial use means either 500 or more annual ***itinerant*** operations, or scheduled commercial service. FAA Order 5090.3C, p. 21 (emphasis added).

(FAA Order 5090.3C does not state that critical aircraft must be the "largest.")

The FAA divides General Aviation operations into two categories, "local" and "itinerant." Itinerant operations are defined as "an operation performed by an aircraft, either IFR, SVFR, or VFR, that lands at an airport, arriving from outside the airport area, or departs an airport and leaves the airport area." [U.S. DOT JO 7210.695, p. 5]. Local operations are defined as "those operations performed by aircraft that remain in the local traffic pattern, execute simulated instrument approaches or low passes at the airport, and the operations to or from the airport and a designated practice area within a 20-mile radius of the tower." *Id*.

The EA, without reference to this distinction, relies on "annual operations" and "total annual operations" not "itinerant operations," *see,* EA, Table 2-1, p. 2-10. Separating itinerant and local operations at ARB would result in a dramatic reduction in the number of annual critical aircraft operations at the airport. For example, data from the website City-Data.com shows that there were 29,322 itinerant operations and 43,573 local operations at ARB in 2007, the year used by MDOT in the EA. *See*, http://www.city-data.com/airports/Ann-Arbor-Michigan.html. In that itinerant operations account for approximately 40% of the total operations at ARB, itinerant B-II operations for 2007 would be in the neighborhood of 300 operations per year [40% of 750 total operations], substantially below the FAA's threshold of 500 annual operations to constitute "substantial use." Moreover, the Airport User Survey shows only 293 annual B-II Small operations at ARB in 2007. [EA Appendix A-1, p. 7]. Thus, the FAA Order 5090.3C airport dimensional standards for B-II small aircraft do not apply.

C. Shifting Runway 6/24 150 Feet to the Southwest Will Not Achieve an Additional Margin of Safety.

The EA states as part of its purpose to "[e]nhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road." [EA, p. 2-5]. Operational safety in low visibility conditions will not be enhanced by providing a clear 34:1 approach surface to Runway 24. The EA is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel. [EA, p. 2-5]. However, in the next paragraph the EA states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles." [EA, p. 2-5]. This statement lacks support in either the Instrument Approach Procedure (IAP) design or Terminal Instrument Procedures ("TERPS") Obstruction Standards.

Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP, and are defined as "Obstacle Identification Surfaces" which do not establish obstacle clearance safety margins, but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety," as stated in the EA, does not apply in the case of these two surfaces. Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions, and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the FAA to accommodate all existing obstructions. Thus, shifting the runway 150' southwest would not enhance safety. Assuming that the EA is correct in the assertion that shifting the Runway 24 threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement, but would result only in a reduction in the required approach visibility minimums. [*See*, attached Williams Aviation Consultants Report]

II. THE EA DOES NOT CONSIDER ALL REASONABLE ALTERNATIVES.

The National Environmental Policy Act ("NEPA") [42 U.S.C. §§ 4321 *et seq.*] requires that federal agencies examine all reasonable alternatives in preparing environmental documents. [42 U.S.C. § 4332(c)(iii)]. An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action is intended to address. The Council on Environmental Quality ("CEQ") Regulations ("NEPA Regulations"), which implement NEPA, require that Federal agencies "[u]se the NEPA process to identify and assess the reasonable alternatives to the proposed actions that will avoid or minimize adverse effects of these actions upon the quality of the human environment" 40 C.F.R. § 1500.2(e), and that "agencies shall . . . (a) Rigorously explore and objectively evaluate all reasonable alternatives . . ." 40 C.F.R. § 1502.14(a). The EA fails to explore all reasonable alternatives to the Preferred Alternative selected.

The EA [p. 2-5] lists five objectives of the proposed project:

- Enhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions.
- Enhance operational safety by improving the FAA ATCT line-of-sight issues.
- Enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road.
- Reduce the occurrence of runway overrun incidents by small category A-I aircraft (local objective).
- Relocate and potentially upgrade the Runway 24 Approach Light System.

As shown in Section I above, enhancing interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions is not a valid need. Further, lengthening Runway 6/24 is not necessary to achieve the remaining four objectives. Those objectives could be met by simply shifting Runway 6/24 150 feet to the southwest, *i.e.*, removing 150 feet from the approach end of Runway 24 and adding 150 feet to the departure end of Runway 24. Runway length would remain 3,505 feet.

Section 2.2.1 of the EA states that a 150-foot shift of the Runway 24 threshold to the west would (1) enhance the safety of ground operations by taxiing aircraft; (2) enhance operational safety, and possibly prevent runway incursions, by expanding the view of the hold area and parallel taxiway to ATCT personnel; (3) allow for a clear 34:1 approach surface to the east end of the runway, providing an added margin of safety between approaching aircraft and ground-based obstacles, which is particularly beneficial when aircraft are operating in low-visibility conditions; and (4) include relocation and replacement of the existing runway approach light system with newer Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF). [EA, pp. 2-5, 2-6]. Shifting Runway 6/24 150 feet to the southwest without lengthening the runway would also accommodate future widening of State Road. Nevertheless, this reasonable alternative was not considered in the EA.

An Environmental Assessment "shall include brief discussions of . . . alternatives . . ." 40 C.F.R. § 1508.9(b).[2] Absent an analysis of an alternative based on a 150-foot southwesterly shift of the runway, without lengthening the runway, the EA is inadequate.

III. THE EA FAILS TO ADEQUATELY ANALYZE OR DISCLOSE THE PROJECT'S AIR QUALITY IMPACTS WHERE IT FAILS TO ADDRESS OR DETERMINE THE PROJECT'S CLEAN AIR ACT CONFORMITY.

Section 7506 of the Federal Clean Air Act [42 U.S.C. §§ 7401 *et seq.*] mandates that "[n]o department, agency, or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to [a State Implementation Plan] after it has been approved or promulgated under [42 U.S.C. § 7410]." The Environmental Protection Agency (EPA) has promulgated regulations implementing Section 7506 (the "Conformity Provision") in 40 C.F.R. §§ 93.150 *et seq.* ("General Conformity Rule"). The General Conformity Rule requires, in part, that Federal agencies first determine if a project is either exempt from conformity analysis or presumed to conform. If it is neither, the agency must conduct a conformity applicability analysis to determine if a full conformity determination is required. *See*, *Air Quality Procedures for Civilian Airports and Air Force Bases*, p. 13.

The project area, *i.e.*, Washtenaw County, is in attainment for five of the seven criteria pollutants [p. 4-17], and marginal nonattainment for Ozone [p. C-3].[3] The area is designated as in nonattainment for $PM_{2.5}$. [EA, p. C-4]. Therefore, one of the following must apply: (1) the Project is exempt from conformity; or (2) the Project is presumed to conform; or (3) the agency must conduct a conformity applicability analysis to determine if a conformity determination for $PM_{2.5}$ is required. The EA does not indicate that any of the required actions was performed.

---

2 Courts have consistently held that the "existence of reasonable but unexamined alternatives renders an EIS inadequate." *See, e.g., Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998).

3 The original six criteria pollutants are Ozone (O3), Particulate Matter (PM_{10}), Carbon Monoxide (CO), Nitrogen Oxides (NO2), Sulfur Dioxide (SO2) and Lead (Pb). FAA Order 1050.1E ("Environmental Impacts; Policies and Procedures"), p. A-3, ¶ 2.1b, includes both PM_{10} and $PM_{2.5}$ under the category Particulate Matter. On April 5, 2010 the EPA published Revisions to the General Conformity Regulations Final Rule [75 Fed. Reg. 17254-279 (2010)] which, among other things, added $PM_{2.5}$ to the list of criteria pollutants in 40 C.F.R. § 93.153(b).

As a threshold matter, the EA is internally inconsistent with regard to whether the Project is exempt or presumed to conform. At page C-4, the EA states unequivocally that "[f]or this analysis it will be assumed that the project is neither exempt nor presumed to conform." [Emphasis added.] However, at page C-5 the EA states ". . . a conformity determination is not required and the proposed project is presumed to conform to the state implementation plan." [Emphasis added.] Under either scenario, however, the EA is deficient and fails to meet the "public disclosure" requirement under the National Environmental Policy Act ("NEPA"), 42 U.S.C. §§ 4321 *et seq*.

A. The EA Fails to Establish That the Project Is Exempt.

A federal agency has two options to determine that a project is exempt from conformity analysis: (1) if the project is included in the list of exempt actions listed in § 93.153(c)(2); or (2) if the project's total of direct and indirect emissions are below the emissions levels specified in § 95.153(b) of the Conformity Regulations ("*de minimis*"). § 93.153(c)(1).

The first option does not apply here because runway and taxiway extension projects such as the one described in the EA [p. 2-1] are not included in the exempt actions listed in § 93.153(c)(2). Nor does the EA establish that the Project can be considered exempt as *de minimis* under 40 C.F.R. § 93.153(c)(1). The EA instead relies on a 1996 MDOT Bureau of Aeronautics Air Quality Study of seven general aviation airports (which notably do not include ARB) for the conclusion that "typical GA airports generate a low level of pollutants." [EA, p. 4-17]. From that nonspecific conclusion, the EA further generalizes to the assertion that, because ARB is comparable in size and activity to the seven airports studied, it can be assumed that emissions resulting from the Project will not exceed the conformity threshold levels and, on that basis, concludes that a conformity analysis is not required.

This assumption is fatally flawed, however, for at least two reasons: (1) the EA does not quantify $PM_{2.5}$ emissions from flight operations at ARB at all, relying exclusively on the 1996 Study; and (2) because there is no quantification, there is also no comparison with the explicit *de minimis* thresholds established in 40 C.F.R. § 93.153(c)(1). It is correct that the original version of 40 C.F.R. § 93.153(c)(1) did not establish explicit thresholds for $PM_{2.5}$, as distinguished from PM_{10}. However, the newly implemented revised General Conformity Rule does establish that distinction, and now serves as the template for the air quality analysis required in the EA. Moreover, FAA Order 1050.1E, Appendix A, p. A3, § 2.16 includes both PM_{10} and $PM_{2.5}$ in "particulate matter."

B. The EA Fails to Establish That the Project Is Presumed to Conform.

The second option, the presumption of conformity does not apply here either. In July, 2007, the FAA published a "Federal Presumed to Conform Actions Under General Conformity Final Notice" [72 Fed.Reg. 41,565-580 (July 2007)] in which the FAA listed fifteen Airport Project categories which the FAA presumes to conform to applicable SIPs. The runway and taxiway extension project described in the EA does not fall within any of those presumed to conform categories. Therefore, the FAA cannot rely on the Presumed to Conform Final Notice to presume that the Project is in conformity.

C. The EA Fails to Establish the Project's Conformity Status.

Finally, even if, for argument's sake, the study of airports other than ARB were adequate for air quality analysis of ARB in the EA (which it is not), the 1996 Study would be an inadequate substitute for the required analysis. 40 C.F.R. § 93.159 requires that analyses under the General Conformity Rule be based on, among other things: (1) "the latest planning assumptions," § 93.159(a); and (2) "the latest and most accurate emissions estimation techniques available," § 93.159(b). The 1996, 14-year old, Study patently fails to fall within either, let alone both, of these parameters.

In summary, the EA fails to establish the existence of any of the necessary components of the required finding of conformity for a Federal project, and, thus, is inadequate under both NEPA and the Clean Air Act.

IV. THE EA FAILS TO ACCOUNT FOR WELLS ON AIRPORT PROPERTY.

While Section 4.5.2 of the EA purports to address "Geology, Groundwater, and Soils" affected by the Project, it understates the significance of the fact that water resources are a principal use of the grounds where the airport is located.

"If there is the potential for contamination of an aquifer designated by the [EPA] as a sole or principal drinking water resource for the area, the responsible FAA official needs to consult with the EPA regional office, as required by section 1424(e) of the Safe Drinking Water Act, as amended." FAA Order 1050.1E, pp. A-74, 75, ¶ 17.1c. "When the thresholds indicate that the potential exists for significant water quality impacts, additional analysis in consultation with State or Federal agencies responsible for protecting water quality will be necessary. *Id.*, pp. A-75, A-76, ¶ 17.4a. "If the EA and early consultation [with the EPA] show that there is a potential for exceeding water quality standards [or] identify water quality problems that cannot be avoided or mitigated . . . an EIS may be required. *Id.*, pp. A-75, ¶ 17.3.

There are two issues raised by the Project that require further examination in the EA. First, there is the issue of contamination from the Airport. The Airport is the location of a porous sand/gravel formation that yields a large amount of water for pumping Historically, the land where the Airport is located was originally acquired by the City of Ann Arbor for water rights in 1929. Until recently, 15% of Ann Arbor's water supply came from the three wells located on Airport property. Water Quality Report, 2008, City of Ann Arbor, p. 2 (available at http://www.a2gov.org/government/publicservices/water_treatment/documents/ccr.pdf). Due to the importance of the water supply at ARB, the EA needs to have more than a few passing words ("Based on coordination with the City of Ann Arbor, the proposed runway extension would not impact the water supply wells or the new water supply line (Bahl, 2009)"). [EA, p. 4-20].

Second, paving the area for a runway, roads, *etc.* increases the impervious area on the aquifer. This in turn reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer that it vital to the City of Ann Arbor. Further environmental review should provide detailed analyses of the impact of this increase in impervious surface, as well as the possibility of contamination, currently unexplored in the EA.

V. <u>THE EA FAILS TO ANALYZE THE PRESENCE OF HAZARDOUS WILDLIFE NEAR THE AIRPORT AND FAILS TO PRESENT ANY MANDATORY MITIGATION MEASURES</u>.

FAA Advisory Circular 150/5200-33B ["Hazardous Wildlife Attractants on or Near Airports"] contains standards for land uses that have the potential to attract hazardous wildlife on or near public-use airports. The standards are applicable to airport development projects, including airport construction, expansion and renovation. Airports that have received Federal grant-in-aid assistance must use these standards. [*See,* AC 150/5200-33B, p. ii]. The FAA recommends separation distances of 5,000 feet at airports that do not sell Jet-A fuel, and 10,000 feet at airports that sell Jet-A fuel for hazardous wildlife attractants. [AC 150/5200-33B, p.1]. ARB sells Jet-A fuel.

The FAA also "recommends a distance of 5 statute miles between the farthest edge of the airport's AOA [Air Operations Area] and the hazardous wildlife attractant if the attractant could cause hazardous wildlife movement into or across the approach or departure airspace." [AC 150/5200-33B, p. 1]. Finally, AC 150/5200-33B provides that "[a]irport operators should identify hazardous wildlife attractants and any associated wildlife hazards during any planning process for new airport development projects" [p. 17] and "[t]he FAA will not approve the placement of airport development projects pertaining to aircraft movement in the vicinity of hazardous wildlife attractants without appropriate mitigating measures." [pp. 17-18].

The FAA ranks geese as number three [3] in a list of the relative hazard to aircraft for 25 species groups. [AC 150/5200-33B, Table 1, p. iii]. However, the EA does not disclose that the area surrounding the airport is a prime habitat for large numbers of Canada Geese. EA Appendix F lists 38 species of birds that have either been observed, or for which there has been confirmed or probable breeding in Airport fields during 2006 through 2008. The list does not include Canada Geese. Canada Geese populate waterways on a golf course, in business parks and in neighboring wetlands located west and southwest of the Airport, well within the separation distances prescribed by the FAA.

The preferred alternative (Build Alternative 3) would extend Runway 6/24 950 feet to the southwest. The extension would allow aircraft landing on Runway 6 and departing on Runway 24 to overfly areas populated by Canada Geese at altitudes of less than 100 feet. The EA does not consider this hazardous condition. Even though they are not designated as "special concern", "threatened" or "endangered," the presence of Canada Geese in the Airport area poses a hazard to aircraft operational safety, and should be identified and analyzed in the EA, along with proper mitigation measures.

VI. <u>THE EA DOES NOT ACKNOWLEDGE OR ANALYZE THE PROJECT'S MANIFEST GROWTH-INDUCING IMPACTS</u>.

A Federal agency is required to evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project [40 C.F.R., § 1508.8(b)] and increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). "The growth-inducing effects of [a] project appear to be its raison d'etre." *Id*. The EA ignores this requirement, even though the Project is virtually defined by its growth-inducing impacts. Despite the fact that the EA assumes that the "percent of night and jet operations would remain constant between the existing condition and the future years" [EA, p. 4-2], there is substantial evidence to indicate that the Project will cause a large increase in both types of operations.

As indicated above, there are no weight restrictions that must be lifted to allow the EA's "critical aircraft" to operate at ARB without weight restrictions. The "load restrictions" referenced on page 2-12 refer not to category B-II aircraft, but to higher category aircraft (jets in the C-I and C-II categories) which must currently operate at reduced weights in order to use the 3,505-foot runway. (Required takeoff length is the primary restrictor.) Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, all of which discourage these aircraft from conducting operations at ARB.

For example, a Cessna Citation II (Category B-II) requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and can operate at unrestricted weight from the existing 3,505 foot runway. A Lear 35 (Category C-I), on the other hand, requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,300 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be less than is currently required. Therefore, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Citation jet, which the EA states is a "critical aircraft."

The longer runway will facilitate the loading of additional passengers and baggage on high performance jet aircraft. Also, the ability to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. If the runway is lengthened to 4,300 feet, it is reasonably foreseeable that ARB will become much more attractive to operators of higher performance jet aircraft, such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II), who could then operate at ARB instead of driving to and from Willow Run Airport.

Contrary to the unsupported assertions in the EA [EA, p. 42; Appendix B-1, p. B-4], it is reasonably foreseeable that the fleet mix will change in favor of a higher percentage of jet operations, as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft account for a high percentage of ARB operations. B-II aircraft account for a low percentage of ARB operations.

It is, therefore, reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer haul business jets often occur in the evening hours due to the longer time duration of their trips. Since one of the stated purposes of the EA is to increase interstate commerce, this is not merely an indirect, but also a direct effect, the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Thus, the evidence is clear that the Project will cause an increase in both jet *and* night operations. It is also reasonably foreseeable that these added high-performance jet aircraft operations and night operations will be accompanied by significant noise and air quality impacts. Nevertheless, the EA fails to acknowledge, let alone analyze, these reasonably foreseeable impacts caused by expansion of Airport physical facilities and operational profile and, thus, is inadequate.

VII. NOISE MODELING FOR THE PROJECT FAILED TO INCLUDE INCREASED JET AIRCRAFT AND NIGHTTIME OPERATIONS IN DEVELOPING NOISE CONTOURS.

The FAA's Integrated Noise Model ("INM") was used to model annual operations for the 2009 existing condition, *i.e.*, April 2008 through March 2009 [EA Appendix B-1, p. B-4] and develop 65, 70 and 75 DNL noise contours for the Project. [EA, p. 4-3]. The EA states that "[t]he existing 65 DNL contour does not extend beyond airport property." [EA, p. 4-3]. During the time modeled, jet operations accounted for approximately 2 percent of total operations at ARB, and nighttime operations accounted for 4.2 percent of total operations. [EA, p. 4-2]. The EA states: (1) "[t]he percent of night and jet operations would remain constant between the existing condition and the future years"; (2) "fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives would remain static" [EA, p. 4-2; Appendix B-1, p. B-4]; and "[t]he ARB 2014 proposed project alternative DNL 65 dBA noise contour does not extend beyond airport property." [EA, p. B-6].

However, as shown in Section VI above, the Project will likely facilitate an increased number of night operations, and a change in fleet mix, which will include higher performance jet aircraft. DNL calculations depend on, among other things, forecast numbers of operations, operational fleet mix and times of operation (day verses night). [EA, Appendix B-2, p. B-16]. However, the EA fails to model or assess future increased night operations and fleet mix changes resulting from the Project.

The FAA is required to use INM to produce, among other things: (1) noise contours at the DNL 75 dB, DNL 70 dB and DNL 65 dB levels; (2) analysis within the proposed alternative DNL 65 dB contour to identify noise sensitive areas where noise will increase by DNL 1.5 dB[4]; and (3) analysis within the ***DNL 60-65 dB contours*** to identify noise sensitive areas where noise will increase by DNL 3dB, ***if*** DNL 1.5 dB increases as documented within the DNL 65 dB contour. [FAA Order 1050.1E, Appendix A, p. A-62, ¶ 14.4d].

As the noise modeling failed to take into account the foreseeable increases in nighttime and jet aircraft operations at ARB, the questions of whether the future DNL 65 dB contour will be increased, and to what extent, and whether increased noise levels within the DNL 65 dB contour would necessitate designation of a DNL 60 dB contour remain unanswered.

---

[4] A significant noise impact would occur if analysis shows that the proposed action will cause noise sensitive areas to experience an increase in noise of DNL 1.5 dB or more at or above DNL 65 dB noise exposure when compared to the no action alternative for the same timeframe." [FAA Order 1050.1E, Appendix A, P. A-61, ¶ 14.3]

VIII. THE EA FAILS TO CONSIDER THE POLITICAL JURISDICTIONS AFFECTED BY THE PROJECT.

FAA Order 5050.4B, paragraph 706 provides a format for integrating the NEPA process with special purpose laws outside the scope of NEPA in preparing environmental assessments. Paragraph 706.e.(4) requires that an environmental assessment address "[p]olitical jurisdiction(s) the proposed action would affect." The EA fails to do that. The EA does not disclose that Pittsfield Township, the political jurisdiction in which the Project is located, and neighboring Lodi Township have both passed resolutions opposing the Project. The EA also fails to identify or analyze the effect that environmental impacts, which are certain to result from the Project (*e.g.*, noise, air quality, safety, economic impacts, *etc.*), will have on those political jurisdictions.

IX. CONCLUSION.

Given the Project's many potential significant environmental impacts that have not been identified or analyzed in the EA, a full Environmental Impact Statement (EIS) is required prior to approval and implementation of the Project. "No matter how thorough, an EA can never substitute for preparation of an EIS, if the proposed action could significantly affect the environment." *Anderson v. Evans*, 371 F.3d 475, 494 (9th Cir. 2004).

Williams Aviation Consultants

Williams Aviation Consultants, Inc. was retained by the law firm of Chevalier, Allen & Lichman, LLP to review and comment on Chapters 1 and 2, and Appendices A and B of the DRAFT Ann Arbor Municipal Airport Environmental Assessment (DEA), February, 2010. The following are our comments on the DEA.

A. Accommodating the Critical Aircraft at Ann Arbor Municipal Airport (ARB)

As stated in paragraph 2.2.7, "*The proposed shift and extension of primary Runway 6/24 at ARB would provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility.* (Emphasis added)

In particular, the proposed project would provide the following benefits:

- *Enhance business aviation and interstate commerce by providing sufficient runway length to allow the majority of category B-II Small critical aircraft that currently use ARB to operate without load restrictions (i.e. reduction in passengers, cargo, and fuel associated with aircraft range).* (Emphasis added)

According to paragraph 2.2, Purpose and Need, "The purpose of the proposed improvements at ARB is to provide facilities that more effectively and efficiently *accommodate the critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport. (Emphasis added)

The critical aircraft is defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the critical aircraft weigh less than 60,000 lbs, a classification of aircraft is used rather than a specific individual aircraft model. A recent Airport User Survey has confirmed that the critical aircraft classification for ARB is "*B-II Small Aircraft.*" (Emphasis added)

Also stated under "Purpose and Need" "*Development of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions).* (Emphasis added)

WAC Comment: There are no aircraft in the B-II Small aircraft classification that require a runway length of 4,300 feet to conduct normal operations. All B-II Small Aircraft are capable of operating out of the current runway (3,505 feet long) without the need to reduce weight by off-loading passengers, baggage or fuel.

Regarding the establishment of the <u>critical aircraft</u>, ARB lacks the required number of 500 annual operations by B-II Small Aircraft, so they have added larger aircraft such as B-II Large, Category C-I and C-II operations to meet the 500 classification requirement. It is the Category C-I and C-II aircraft which would benefit by the runway extension to 4,300 feet, not

8490 South Power Road, Suite 105-181 • Gilbert, AZ 85297 • Office (480) 987-7823 • Fax (602) 513-7388

those aircraft that fall within the definition of Category B-II Small Aircraft. The current runway length of 3,500 feet is sufficient to handle all Category B-II Small Aircraft.

B. Lengthening Runway 6/24 to 4,300 Feet: The Impact on Aircraft Load Restrictions and Fleet Mix

The "load restrictions" referenced above in paragraph 2.2.7 refer to the fact that the higher category aircraft (primarily jets in the C-I and C-II categories) must currently operate at reduced weights in order to operate out of the current 3,500 foot runway (required takeoff length is the primary restrictor). Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel; all of which discourage these aircraft from conducting operations out of ARB.

For example: A Cessna Citation II (Category B-II) requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day and may therefore operate unrestricted as to weight from the current 3,500 foot runway. A Lear 35 (Category C-I) requires 5,000 feet for takeoff at maximum certificated gross weight on the same standard day.

The Category B-II Citation II can conduct unrestricted operations from the current 3,500 foot runway. Whereas extending the runway to 4,300 feet would not facilitate unrestricted operations by the Category C–I, Lear 35, the required weight reduction would be less than is currently required. In this way, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Small Citation jet, or any other Category B-II Small aircraft.

All Category B-II Small aircraft, i.e. the ARB critical design aircraft, are currently accommodated on the existing 3,500 foot runway. Contrary to what is stated in the DEA, lengthening the runway to 4,300 feet WOULD NOT "provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility."

If the runway is lengthened to 4,300 feet, other jets such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II) may be able to operate out of ARB with minor reductions in takeoff weight. This will impact the community as it could reasonably be expected that the longer runway will attract more of the larger, higher performance jet aircraft to the airport.

These added high performance jet aircraft operations will be accompanied by noise and air quality impacts. Many of these operations will take place at night, thereby negatively affecting the general quiet of the surrounding community.

C. **Shifting Runway 6/24 150 Feet to the West While Maintaining the Current Runway Length of 3,500 Feet: The Impact on Load Restrictions, Future Fleet Mix and Safety of Operations**

Load Restrictions

Maintaining the current runway length of 3,500 feet would mean that the Category C-1 and C-II aircraft would continue to suffer significant load restrictions. These load restrictions would thereby continue to serve as a deterrent to these aircraft operating out of ARB.

Future Fleet Mix

Maintaining the current runway length would serve to maintain the current fleet mix. Category B-II Small jet aircraft include lower powered models such as the smaller versions of the Cessna Citation (Category B-I/II) and the Mitsubishi Diamond jet (Category B-I). Higher powered jet aircraft such as the Lear 25 (Category C-I), Lear 35 (Category C-I), IAI Astra (Category C-I) and Cessna Citation III (Category C-II) may be generally discouraged from flying into Ann Arbor and would generally, with few exceptions choose to land at Detroit and drive the 40 miles to Ann Arbor.

Safety of Operations

2.2.1 Safety Enhancements:

In the first paragraph, the consultant is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel.

However, in the next paragraph the consultant states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles."

This statement betrays a lack of understanding by the consultant of Instrument Approach Procedure (IAP) design and TERPS Obstruction Standards. Regarding the 20:1 and the 34:1 surfaces; it is not either/or, but both/and. Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP and are defined as "Obstacle Identification Surfaces" which do not establish obstacle clearance safety margins but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety" as stated by the consultant does not apply in the case of these two surfaces.

Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the

FAA to accommodate all existing obstructions. In this respect, shifting the runway 150' to the west would not enhance safety.

Summary: Assuming that the consultant is correct in their assertion that shifting the threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement but would only result in a reduction in the required approach visibility minimums.

D. Appendix B Noise Analysis Report
B-1 Noise Impact Analysis
B.1.3 Data
Flight Operations

The consultant states "INM-modeled annual operations for the 2009 existing condition, consisting of operations from April 2008 through March 2009, totaled 61,969 operations, which is approximately 169 daily operations. Jet operations accounted for approximately 2 percent of the total operations. Nighttime operations accounted for 4.2 percent of the total operations."

2014 future condition aircraft operations were obtained from the 2008 FAA TAF for ARB. Modeled annual operations for the 2014 condition totaled 69,717 operations, or approximately 191 daily operations. *It is assumed that the percent of night and jet operations will remain constant between the existing condition and the future years. In addition, it is also assumed that the fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives will remain static.* The existing and future fleet mix with annual operations is shown in Table B-2." (Emphasis added)

The consultant wrongly assumes that the percent of night and jet operations will remain constant, and that the fleet mix will remain static if Runway 6/24 is lengthened to 4,300 feet.

The longer runway will make ARB much more attractive to larger and higher performance jet aircraft as the added runway length will facilitate the loading of additional passengers and baggage on to these aircraft. Also, being able to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. As ARB becomes more attractive to higher performance jet aircraft, these larger aircraft may then consider operations to/from ARB in lieu of landing at Detroit and driving to Ann Arbor.

As more high performance jet aircraft begin operations at ARB, the fleet mix will change in favor of a higher percentage of jet operations as compared to the current level of light single and multiengine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft currently reflect a high percentage of ARB operations. B-II Small aircraft (the critical design aircraft) reflect a low percentage of ARB operations. Recall that Category B-II Large and Category C aircraft had to be added to the currently operating Category B-II Small aircraft design group in order to meet the 500 operation requirement for establishing the critical aircraft and thereby justify the runway extension.

The number of night operations also has the strong potential to increase as the number of arrivals of the larger, longer haul business jets often occur in the evening hours due to the longer time duration of their trips. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Steve Houtteman
Environmental Specialist
MDOT-Office of Aeronautics
2700 Port Lansing Road
Lansing, MI 48906-2160

Re: Comments of Pittsfield Charter Township and the Committee for Preserving Community Quality on Michigan Department of Transportation's revised Draft Environmental Assessment for the Extension of the Runway at Ann Arbor Municipal Airport.

Dear Mr. Houtteman:

The following comments are submitted on behalf of The Charter Township of Pittsfield and the Committee for Preserving Community Quality (CPCQ) on the revised Draft Environmental Assessment (RDEA) dated October, 2016, but not released and published for public comment until January, 2017, prepared for the City of Ann Arbor ("City"), the Michigan Department of Transportation, Aeronautics Division (MDOT) and the Federal Aviation Administration (FAA).

The RDEA became necessary when MDOT failed to proceed to a final Environmental Assessment in a timely fashion. The original Draft Environmental Assessment (DEA), which was published on February 28, 2010, contained numerous problems and issues that were identified in comments by Pittsfield Township, CPCQ, Washtenaw County and the Federal Aviation Administration, among others. While the RDEA addresses some of

1 LEAGUE, #60036 | IRVINE, CA 92602 | TEL 949.735.8217 | FAX 714.707.4282 | staber@taberlawgroup.com

the issues raised in those comments, it fails to address all concerns that were raised previously while creating additional problems. The RDEA is seriously flawed for numerous reasons detailed below and it should not be approved.

I. THE RDEA DOES NOT SUPPORT ITS PURPOSE AND NEED: THERE IS NO PURPOSE OR NEED FOR THE PREFERRED ALTERNATIVE.

An environmental assessment (EA) must include a discussion of the purpose and need for the proposed action which must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." 40 C.F.R. § 1502.13. In addressing the Purpose and Need section of an EA, FAA Order 1050.1F provides that the Purpose and Need section "presents the problem being addressed and describes what the FAA is trying to achieve with the proposed action. The purpose and need for the proposed action must be clearly explained and stated in terms that are understandable to individuals who are not familiar with aviation or commercial aerospace activities. To provide context while keeping this section of the EA brief, the FAA may incorporate by reference any supporting data, inventories, assessments, analyses, or studies." FAA Order 1050.1F, ¶ 6-2.1c. The RDEA's Purpose and Need accomplishes none of these goals.

A. The RDEA Cannot Support Its Assertion That ARB Is a "B-II" Airport or that the Runway Expansion Is Needed by Aircraft that Make Substantial Use of the Airport.

The RDEA does not present a convincing case that "B-II" aircraft are the "critical aircraft" for ARB. Moreover, any lengthening of the runway would substantially serve only a couple of aircraft that currently use ARB, while attracting larger and noisier aircraft.

TABER LAW GROUP PC

1. In Four of the Last Five Years the 500 Operations Has Not Been Met.

Recommended runway lengths for airports are contained in MDOT's Michigan Airport Survey Program (MASP) (the most current version of which is 2008) or FAA Advisory Circular 150/5300-13 *Airport Design.* In either case, the recommended runway length is established by the "critical aircraft" for the airport in question. The RDEA states, without attribution, that a "critical aircraft" is "defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport." RDEA, p.12. However, that is incorrect. FAA Order 5090.3C, *Field Formulation of the National Plan of Integrated Airport Systems (NPIAS)* states:

> 3-4. AIRPORT DIMENSIONAL STANDARDS Airport dimensional standards (such as runway length and width, separation standards, surface gradients, etc.) should be selected which are appropriate for the **critical aircraft that will make substantial use of the airport in the planning period.** Substantial use means either 500 or more annual itinerant operations, or scheduled commercial service. **The critical aircraft may be a single aircraft or a composite of the most demanding characteristics of several aircraf**t. The critical aircraft (or composite aircraft) is used to identify the appropriate Airport Reference Code for airport design criteria. Design criteria (such as dimensional standards and appropriate pavement strength) are contained within AC 150-5300-13, Airport Design.

FAA Order 5090.3C, p.21 (emphasis added). The RDEA has claimed that the critical aircraft for ARB is "B-II." That is, aircraft with an approach speed of 91 NMPH but less than 121 NMPH, a wingspan of 49 ft., but less than 79 ft., and a tail height of 20 ft., but less than 30 ft. However, in four of the last eight years, B-II aircraft have not used ARB for over 500 operations, the threshold for determining whether there is "substantial use."

Using the FAA's Traffic Flow Management System Counts[1], it is apparent that since 2009, only four years have exceeded the 500 operations for B-II aircraft (both small and large). Since the original DEA was published in 2010, there have been only two years that exceeded the 500 operations threshold.

Year	Number of B-II Operations
2009	553
2010	554
2011	512
2012	444
2013	481
2014	538
2015	429
2016	447

Source: FAA Traffic Flow Management System Counts https:/aspm/faa.gov/tfms/sys/Airport.asp

Therefore, it is incorrect to conclude that "B-II" aircraft is the "critical aircraft" for ARB. Because the aircraft classification "B-II" is not the critical aircraft, the runway does not need to be lengthened to accommodate that size of aircraft.

2. The operating specifications for one aircraft is driving ARB's push to lengthen the primary runway.

Since 2009, approximately two-thirds of all "B-II" operations come from two aircraft: a Cessna Citation XLS[2] and a Beechcraft King Air 200.

[1] MDOT uses FAA's Traffic Flow Management System Counts (TFMSC) for its 2014 "User Survey." TFMSC is available to the public at https://aspm/faa.gov/tfms/sys/Airport.asp.
[2] Most, if not all, of the "pilot quotes" regarding the need for the expansion of the runway come from the corporate pilot of the Cessna Citation Excel.

Year	No. of Citation XLS Flights	Percentage of All B-II Flights	No. of Beechcraft King Air 200 Flts	Percentage of All B-II Flights	King Air & XLS Flights as % of All B-II Flts
2016	153	34%	127	28%	63%
2015	188	44%	108	25%	69%
2014	158	29%	167	31%	60%
2013	148	31%	113	24%	54%
2012	164	37%	120	27%	64%
2011	197	38%	151	30%	68%
2010	179	32%	201	36%	69%
2009	198	36%	152	27%	63%

Source: FAA Traffic Flow Management System Counts https:/aspm/faa.gov/tfms/sys/Airport.asp

Thus, the Project primarily benefits two aircraft out of the entire fleet of aircraft that are based and/or use ARB on a regular basis. The question becomes whether this is a proper "purpose and need" to expend over $3 million in federal funds on a Project[3] that primarily benefits two aircraft.

The "purpose and need" of the Project comes under additional scrutiny when one considers the take-off/landing distances specified for the various B-II aircraft that use ARB on a regular basis. Since the "need" is "to allow the critical aircraft to safely operate at their optimum capabilities without weight restrictions due to lack of suitable runway length" (RDEA, p.12) it is important to understand what the "optimum capabilities" for "critical aircraft" are.

[3] As used in these comments, the term "Project" means what the RDEA identifies as the "preferred alternative."

Aircraft Model	**No. of 2014 Operations**	**Take-off distance (MTOW, Sea Level, ISA)**	**Landing Distance**
B-II Small			
Aero Commander 500	1	1,916	2,235
Gulfstream Jetprop Commander 1000	3	2,131	2,186
Beechcraft King Air 90	67	2,856	2,275
Beechcraft King Air 100	34	2,694	2,679
Beechcraft King Air 200	167	2,579	2,074
Cessna 441 Conquest II	5	2,465	1,875
Cessna Citation CJ2 (C25A)	2	3,360	2,980
B-II Large			
Beechcraft King Air 300	5	3,300	2,692
Beechcraft King Air 350	16	3,300	2,692
Cessna Citation CJ3 (C25B)	4	3,180	2,770
Cessna Citation II (C550)	2	3,450	2,078
Cessna Citation V (C560)	46	3,160	2,230
Cessna Citation Excel (C56X)	158	3,590	2,909
Embraer Phenom 300	28	3,199	2,430

Multiple Sources

Therefore, extending the runway is necessary for the Cessna Citation Excel and for the Cessna Citation II. All other B-II aircraft can use ARB's 3,500-foot runway with little or no weight restrictions. The Beechcraft King Air 200 can use ARB's 3,500-foot runway on most days with little or no weight restrictions. The entire runway expansion project will primarily benefit a single aircraft. Therefore, either the project is intended to allow an increase in the number of larger aircraft operations at ARB, which the RDEA claims is not the case, or it is meant to primarily benefit a single aircraft.

B. RDEA's "Need" Is Not Supported by Evidence in the RDEA

Beyond this, the problem being addressed – Need – is not supported by any substantive evidence in the RDEA. None of the inventories, assessments, analyses, or studies required by FAA Order 1050.1F are present in the RDEA. FAA Order 1050.1F, ¶ 6-2.1c. No actual evidence of economic losses because of weight restrictions are provided. In fact, there is no evidence, except for a single quote from the Cessna Citation XLS pilot, that operating a B-II aircraft at ARB requires the use of weight restrictions. MDOT relies entirely on its findings that ARB is a "B-II" airport. Both the MASP 2008 and the FAA advisory circular **recommend** a runway length of 4,300 and 4,200 (respectively) for B-II aircraft. There is no discussion in the RDEA that operating with weight restriction is an issue at ARB for anyone except with the pilot of the Citation XLS.

It is understood that the distances listed above are at sea level (which ARB is not) and on a "standard day." However, without more information from ARB regarding weight restrictions faced by the current users, it is the best information we have to examine ARB's claims that weight restrictions are "frequently" imposed on B-II aircraft. MDOT maintains that it is desirable to allow critical aircraft to operate at their optimum capabilities, yet MDOT does not provide any information about how often critical aircraft cannot operate at their optimum capabilities or even what those optimum capabilities are. Until that information is provided, the Project must not be approved.

ARB has consistently maintained that it need not quantify load restrictions or answer any questions about how often load restrictions occur at ARB because no other airport in Michigan has been required to do so. However, ARB has made "operating without load restrictions" a critical component of its purpose and need, so it should also have to reveal how big a factor this really is and show that the Project will not primarily benefit a single aircraft.

Also, MDOT is aware that, according to the National Weather Service, temperatures exceed 40 degrees Fahrenheit nine months out of the year in Ann Arbor (Exhibit 1). This fact suggests that instead of an expensive and potentially dangerous runway expansion, a more appropriate solution is that the single aircraft in question be based at another larger airport (Willow Run is just 12 miles away). Even the FAA queried: "[t]his example seems to be an extreme case. . .Why do they base at ARB instead of another close airport if they cannot use the aircraft to it's (sic) max capability above 40 degree F?" (Comment No. 15, October 2016 MDOT AERO / Applicant Ann Arbor comments in response to FAA questions.) And in a related question (Comment No. 8), the FAA asked, ". . .how often is the runway length affecting users?" – a question that went unanswered by RDEA.

C. Lengthened Runway Would Be Rarely Required, But Could Pose Risks to the Surrounding Community Every Day.

While the RDEA does not provide any data on B-II operational usage in terms of the number of days when aircraft suffered actual weight penalties, number of aircraft involved, or the actual penalties suffered on the current runway, it is possible to provide an analysis based on usage data of how frequently the expanded runway might be necessary. A statistical analysis makes such a determination possible. FAA Advisory Circular 150/5325-4B *Runway Length Requirements for Airport Design* aids an airport in determining the recommended runway length. AC 150/5325-4B, contains a runway length curve that was utilized with temperatures at 83 degrees Fahrenheit or above, and an ARB elevation of 839 feet, criteria to which MDOT stipulated meet the mean daily temperature during the hottest month at ARB. RDEA, Appendix K, Response No. 75. ARB also had 57,370 total operations in 2014, of which, it claims, 551 were category B-II operations. RDEA, Table 1-1. An analysis of data from the National Oceanic and Atmospheric Administration Weather Station at ARB shows in the most recent year (2015) there were 42

TABER LAW GROUP PC

days in which the temperature was 83 degrees Fahrenheit or above. ARB currently has a based population of 183 aircraft, of which 14 are category B-II aircraft. RDEA, § 1.2, ¶ 2.

With these data, a calculation of potential need of an expanded runway based on maximum potential need can be made. If, on every day on which the temperature reached or exceeded 83 degrees, every aircraft in the B-II fleet operated at its maximum take-off weight – a highly unlikely possibility – and required the expanded runway to take-off, based on the ARB fleet population the need for the expanded runway would be 0.0088, or less than 1 in 100 (42/365 x 14/183). This is based on the number of days with temperatures exceeding 83 degrees and the proportion of the total ARB fleet that is Category B-II. However, if this calculation were based on the more realistic actual usage that took place in the most recent operational year (2014) used in the RDEA, based on the same criteria, on every day the temperature reached 83 degrees or above, the actual need for an expanded runway would be 0.00110 – or about 1 in 1,000 (42/365 x 551/57,370) – the number of B-II operations relative to the total operations in the most recent year of 2014.

Thus, operational need for an expanded runway would be quite rare, at best – if at all. Based on statistical analysis the expanded runway would be used for approximately 50 operations per year, at most. Yet, it would place citizens in the surrounding community at risk hundreds of times more frequently. This is due to the fact that aircraft would be taking off and landing 950 feet closer to residential areas, and larger and heavier aircraft, which undoubtedly will be attracted to ARB by the expanded runway.[4] These risks are exacerbated because of the potential dangers posed by aircraft that would be landing just 93 feet over homes in an area heavily populated with Canada geese just west of the airport, and by the reduced margin of safety in the event a heavy twin-engine aircraft suffers an engine failure on or just after takeoff. Such aircraft can lose their climbing power with an engine loss and could

[4] MDOT and ARB consistently assume that the fleet mix and number of annual operations by larger, faster aircraft will remain the essentially the same after the runway has been lengthened. This is a false assumption. *See infra* IV.B.2, p.30.

crash into the heavily populated neighborhood. The risk of – and liability from -- such a potential accident has not been thoroughly studied, and is not assessed in the RDEA.

D. The RDEA Conflates Purpose and Need.

The RDEA stated the document was prepared to conform to the requirements of FAA Order 1050.1F, "Environmental Impact: Policies and Procedures." Section 6-2.1(c) of Order 1050.1F defines need (the problem being addressed) and purpose (the proposed solution to the problem), saying they must be "clearly explained and stated in terms that are understandable to individuals who are not familiar with aviation or commercial airspace activities." The Order further recommends incorporating "by reference any supporting data, inventories, assessments, analyses, or studies." The Order clearly distinguishes Purpose and Need. The Purpose (*i.e.,* the Project) is supposed to resolve the Need (*i.e.,* the problem). Here, the desire for the Project is what is driving the Project. As such, this is a case of a Purpose looking for a Need. That is, it is a project looking for a problem to justify its existence.

The RDEA does not fulfill the requirements of FAA Order 1050.1F. The RDEA is flawed in stating in § 1.4 on Purpose and Need that a problem actually exists, and by using confusing language to conflate Need and Purpose as a result. The claimed Need lacks substantive evidence. Section 1.4 of the RDEA states "Need of the proposed actions is to allow the critical aircraft to safely operate at their optimum capabilities without weight restrictions (i.e. reductions in passengers, cargo, and fuel associated with cargo range) due to suitable runway length." RDEA, p.12, ¶ 7. But that presumes that such critical aircraft cannot already operate at such capabilities. The only purported evidence to support such a claim contained in the RDEA is the comment from the Cessna Citation XLS pilot who claimed, "…we are forced to reduce our departure weight with any temperature above 40 degrees Fahrenheit…which in many cases causes us an additional fueling stop which could be avoided with a longer runway…" RDEA, p.13, ¶ 6. In responding to

FAA's October 2016 comments, MDOT claimed that the pilot uses ARB due to the "proximity" of ARB to the user's business which offers "a significant time savings over other local airports." Since Willow Run Airport (YIP) is a short 12 miles from ARB (15 minutes by car), it is hard to imagine how using ARB would offer a "significant time savings." Thus, MDOT is arguing that the runway needs to be lengthened so that one pilot does not have to drive an extra 12 miles to get to/from his office on the handful of days that a weight restriction would be required.

The remaining evidence presented to support the Need claim relies on resolving an operational safety line-of-sight issue involving the FAA Air Traffic Control Tower. However, that issue could be resolved by the much shorter proposed 150-foot shift alone, described elsewhere in the RDEA (RDEA, § 2.1.4, "150-Foot Runway Shift Only"), not requiring the larger 800-foot runway expansion in addition to the 150-foot shift, which was not even fully studied as an alternative.

MDOT then attempts to explain the Purpose of the expansion to "fully accommodate the operational requirements of critical aircraft currently using the airport," while at the same time enhancing safety. For this, the applicant relies on FAA Advisory Circular 150/5325-4B, *Runway Length Requirements for Airport Design*, which suggests a runway of the length proposed for its determination of the recommended B-II classification of the critical aircraft for ARB. However, in utilizing the Advisory Circular and no supporting documentation as the primary justification for the proposed expansion, the RDEA establishes a Purpose to solve a problem for which a Need has not been substantially established.

This issue of Need justification was also problematic in the original DEA, which was issued in 2010, causing the FAA to also question the Need issue. In its May, 2010 comments on the 2010 DEA, the FAA asked, "[h]as it been documented that the current B-II 'small' users operate with load restrictions? If so, how often does this occur and what are the quantifiable impacts to their operations?" RDEA, Appendix J, FAA Letter dated 5-13-10, p.6, ¶ 5). In addition, in a separate question, the FAA asked, "the conclusion for the implementation for the preferred alternative states that a positive result of improvements is the ability of business owners to achieve improved fleet efficiency for critical aircraft by maximizing their passenger and/or cargo loads. How has this statement been substantiated? What records exist that current users at ARB are not operating at maximum passenger and/or cargo loads? What has been the economic impact of the reduction of loads if they are occurring?" RDEA, Appendix J, FAA Letter dated 5-13-10, p.7, ¶ 6.). None of these questions have been answered. They must be answered before the project is approved.

MDOT and ARB respond by again conflating Purpose and Need. In Comment No. 48 of the RDEA (RDEA, Appendix K), MDOT and ARB detail AC 150/5325-4B justification for aircraft family groupings of similar performance characteristics, as well as attempting to justify an explanation for its recommended proposal to expand ARB's primary runway to a 4,300-foot length based on runway length curves contained in the AC. The response concludes that "…load factors are only considered in the development of recommended runway lengths for critical aircraft groupings and individual aircraft models in the 'large' weight category. Load factor analysis is not a requirement for determining the recommended runway length at small general aviation airports such as ARB, with critical aircraft models in the B-II 'small' category. Since the FAA's methodology of determining the recommended runway length at ARB does not consider load factors, no in-depth analysis of aircraft loading was conducted as part of this study…" *Id.*, ¶ 7; *see also* Response to FAA's October, 2016, Comments, No. 8.

MDOT goes on to emphasize that "no other small general aviation airport in Michigan has ever had load factors analyzed as part of developing justification for extension of their primary runway to the length recommended in the FAA AC." RDEA, Appendix K, Comment 48, ¶ 7. The fact that this has never been required by MDOT is not a justification for avoiding answering the FAA's questions regarding the sufficiency of the existing ARB runway and the assumed Need for runway expansion, or adhering to the recommended procedures in the FAA AC. For more than two decades, MDOT had served as the FAA's agent in Michigan under the federal block grant program (49 U.S.C. § 47128), but its precedents may not always affirm the most proper enforcement of FAA-intended policies. A more rigorous agent might have pursued more thorough and complete standards and analyses with respect to ARB's critical usage and justification for expansion. It is also worth noting, as an aside, that MDOT's federal block grant status could be at risk if it does not more fully enforce the requirements under FAA Order 1050.1F in terms of requiring applicants to provide supporting data, inventories, assessments, analyses, or studies to support their proposed expansions, even though MDOT has not traditionally done so.

The point is that the "Need" must be justified in keeping with the full requirements of FAA Order 1050.1F to avoid taxpayer dollars being wasted on airport runway construction that may not be necessary or justified, which could lead to unnecessary spending across America if the Order were not fully and properly enforced.

If the Purpose and Need requirement has not been fully and properly enforced for the 20-plus years MDOT has served as the FAA's agent in Michigan, that is insufficient justification to allow such negligence to serve as a precedent. This example, for instance, presumes the only reason for the FAA's questions would be to substantiate Purpose. And yet that defies logic on its face because the FAA issues an Advisory Circular with advice on runway length development to satisfy any Purpose requirement for B-II airports. It is a much more reasonable conclusion to assume the FAA's questions pertain to Need. To paraphrase the FAA's questions, to-wit, if there is no established, substantiated loss of passenger or cargo load opportunities, or established current negative economic impact, there is no Need. Thus, the only way the applicant Ann Arbor could establish Need was to conflate it with Purpose, as it has done in the current RDEA, further confusing readers by attempting to justify the claimed Need based on an FAA Advisory Circular rather than the requirements of an FAA Order. This does not establish a proper Need for the proposed expansion.

TABER LAW GROUP PC

E. While Claims of Enhancements to Interstate Commerce Are overstated, Runway expansion Could Cost Local Authorities Millions in Losses from Reduced Taxes.

The RDEA claims an expanded runway would provide enhancements to interstate commerce by "removal of operational weight restrictions on critical category aircraft." RDEA, § 1.8.4. But the RDEA does not establish through specific operational statistical evidence that current critical aircraft suffer interstate commerce penalties causing economic hardship. In fact, elsewhere in the RDEA, when asked directly by the FAA to provide evidence on how the project would enhance interstate commerce in response to the 2010 DEA (RDEA, Appendix K, Response No. 30, ¶ 1), MDOT stated that "the need for the project is not based on the enhancement of interstate commerce. . .Enhancement of interstate commerce is a benefit of providing a runway long enough to avoid weight restrictions to critical aircraft. . ." Thus, the only condition that provides for a claim of enhanced interstate commerce is the same one that provides for the flawed one of satisfying Purpose and Need – conflating both, and then utilizing the FAA's Advisory Circular on recommended runway length curves to infer a loss of interstate commerce. Indeed, there is nothing to suggest that the "enhancement of interstate commerce" would simply mean moving the "interstate commerce" from YIP to ARB.

However, while there is no legitimate economic justification for the runway expansion, there is extensive research to suggest such an expansion could cause economic losses to several communities surrounding the airport, in the form of reduced real estate values and, consequently, reduced property and school taxes based on assessed property values. Extensive research based on other communities in which airport runways have been extended – Atlanta, Reno-Tahoe, Chicago O'Hare, the Greensboro-High Point-Winston Salem metroplex, 23 cities in Canada, among others – show property values decline as runways are expanded. The most respected such study. *The Announcement Effect of an Airport Expansion on Housing Prices*, G.D. Jud & D.T. Winker, (2006),

TABER LAW GROUP PC

JOURNAL OF REAL ESTATE FINANCE AND ECONOMICS, 33, 2, 91-103, suggests house prices decline by about 9.2 percent within a 2.5-mile band of the airport, and, beyond that, in the next 1.5-mile band, prices decline another 5.7 percent once an announcement – without extraneous influences – moved forward. The lengthy hold up of the proposed ARB expansion has represented an extraneous influence since the initial announcement eight years ago, but that if approved, these effects would occur, as well, at ARB. To further support this claim, a literature search could find no published, peer-reviewed research study where residential real estate values continued to rise in areas immediately surrounding an airport after runways were expanded. Further adding credence to this statement, the sales manager of the largest real estate firm in the Ann Arbor area has said he would no longer accept residential house sales listings in the area surrounding ARB if the runway extension is approved.[5]

A decrease in property values in the areas surrounding ARB would have important consequences for the various governmental bodies that benefit from property tax collections. In the corridors referenced in the Jud & Winker study noted above, there are:

- 6,239 Pittsfield Township parcels of land within the 2.5-mile area surrounding the airport; and
- 4,168 parcels within the 2.5-mile to 4-mile area.

These parcels will be subjected to a decline in real estate values of 9.2 percent and 5.7 per cent, respectively due to the expanded runway. Using those facts, the following is the estimated value of what the potential **annual** losses in property tax revenue would be for various governmental bodies based on their tax collections in 2016:

- $1.5 million less for the Ann Arbor School District;
- $1.4 million less for the Saline School District;

[5] Frank McVeigh, Charles Reinhart Company, personal communication.

- $850,000 less for Pittsfield Charter Township; and,
- $810,000 less for Washtenaw County.

This estimate is only for property located in Pittsfield Township. These numbers vastly understate the decline in tax revenues, because they do not consider the potential effects of property in Lodi Township, the City of Saline, (both of which could impact the Saline School District's revenues), or most importantly, property in the City of Ann Arbor. Thus, governments could stand to lose millions of dollars in operating funds annually from a runway expansion project that has yet to demonstrate any real economic benefit.

II. ALL REASONABLE ALTERNATIVES WERE NOT CONSIDERED IN THE RDEA.

The National Environmental Policy Act ("NEPA") (42 U.S.C. §§ 4321 *et seq*.) requires that federal agencies examine all reasonable alternatives in preparing environmental documents. 42 U.S.C. § 4332(c)(iii). An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action is intended to address. The Council on Environmental Quality ("CEQ") Regulations ("NEPA Regulations"), which implement NEPA, require that Federal agencies "[u]se the NEPA process to identify and assess the reasonable alternatives to the proposed actions that will avoid or minimize adverse effects of these actions upon the quality of the human environment" 40 C.F.R. § 1500.2(e), and that "agencies shall . . . (a) Rigorously explore and objectively evaluate all reasonable alternatives…." 40 C.F.R. § 1502.14(a). Courts have consistently held that the "existence of reasonable but unexamined alternatives renders an EIS inadequate." *See*, *e.g*., *Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998). Because the RDEA fails to explore all reasonable alternatives to the Preferred Alternative selected, it is inadequate.

Moreover, the FAA and MDOT, are required to take action if an environmental assessment is limiting the choice of reasonable alternatives. "If the FAA is . . . aware that the applicant is about to take an action within the

TABER LAW GROUP PC

agency's jurisdiction that would have an adverse environmental impact *or limit the choice of reasonable alternatives*, the responsible FAA official will promptly notify the applicant that the FAA will take appropriate action to ensure that the objectives and procedures of NEPA are achieved" 1050.1F, 2-3.1 (emphasis added).

A. The Use of Willow Run Airport Is a "Reasonable Alternative" that Has Not Been Fully Considered.

The RDEA summarily dismisses using Willow Run Airport (YIP) as an alternative because "[i]t was determined that using other airports is neither suitable based on runway lengths nor desirable based on proximity to corporate offices or business needs. Consequently, this alternative was removed from further consideration." RDEA, p.28. Since the not "suitable based on runway lengths" applies only to airports other than YIP, the sole reason why using YIP was dismissed as a "reasonable alternative" is due to its not being "desirable based on proximity to corporate offices or business needs." These are not valid reasons to not consider an alternative in an Environmental Assessment and in violation of NEPA, NEA regulations, and FAA Order 1050.1F.

The RDEA bases its conclusion that ARB is a more "desirable" location on the assumption that B-II aircraft operators using ARB instead of YIP "demonstrates that a large number of operators of business aircraft value the close proximity of ARB to their corporate offices and business contacts over the larger facility at Willow Run." This is a baseless assumption on the part of the RDEA, since it is equally likely that the fact that B-II aircraft still land at ARB instead of YIP demonstrates that the weight restrictions posed by the short runway are non-existent or not significant, otherwise these users would land at YIP instead. Although the FAA raised this point in its October, 2016, comments, the RDEA chose not to address it. FAA October, 2016, Comments, No. 62. Instead, ARB waves the argument off by stating that the Airport "cannot dictate which airfield a pilot uses" – an argument that applies equally as well to the RDEA's argument that rejects the YIP alternative.

However, using YIP instead of ARB meets the purpose and need of the project thereby making it a reasonable alternative that must be considered in the Environmental Assessment. As the RDEA points out, YIP has the runway length and facilities to accommodate the aircraft that may be weight-restricted from using ARB. *See* RDEA, p.27. The only reason that the RDEA gives to dismiss it from further consideration is the fact that it is located 12 miles from ARB and that it is an "inconvenience" to the corporations who want to use ARB instead of YIP. Even if lengthening the runway would benefit more than one or two aircraft, this is not an appropriate reason to dismiss an alternative from further consideration in an Environmental Assessment. If an alternative is "reasonable" (*i.e.,* it meets the purpose and need) then it must be considered in the Environmental Assessment alongside the preferred alternative and the no action alternative. *Friends of Southeast's Future*, at 1065. Since using YIP instead of ARB would achieve the purpose and need of allowing "critical aircraft" to take-off and land without weight restrictions, it is a reasonable alternative and must be considered as part of the Environmental Assessment process. The RDEA must be deemed inadequate on this basis alone

In its response to the FAA's comments in October, 2016, ARB adds additional criteria for dismissing the YIP Alternative by stating that the "proposed project would also result in ARB achieving full compliance with all AERO basic development standards outlined in the MASP 2008 for category B-II airports." However, it is far from clear that ARB is a "B-II" airport since there have not been over 500 itinerant operations of B-II aircraft for the past two years and four of the last five years (*see infra* pp.4-6). Moreover, both the MASP's and the FAA's design standards are recommendations, not requirements, and the FAA has told MDOT that meeting the recommended standards in its advisory circular is not a legitimate basis for lengthening a runway using federal funds. Finally, "achieving full compliance with AERO basic development standards" is *not* part of the Need. Although that may be raised in an environmental assessment as a reason to prefer the preferred alternative over the YIP Alternative, it is not a reason to eliminate the YIP Alternative from further consideration.

TABER LAW GROUP PC

B. Line-of-Sight Shift Only.

The RDEA lists four "benefits" of the Project:

1. Provide sufficient runway length to allow the majority of category B-II Small critical aircraft that currently use ARB to operate without load restrictions (*i.e.* reduction in passengers, cargo, and fuel associated with aircraft range);

2. Enhance the safety of ground operations, and lessen the chances of a runway incursion, by expanding the view of the parallel taxiway and aircraft hold area to ATCT personnel;

3. Improve the all-weather capability of ARB and enhance operational safety in low visibility conditions by providing a clear 34:1 approach slope to Runway 24; and

4. Address the local objective of decreasing the number of runway overruns by small category A-I aircraft by providing approximately 795 feet of additional runway pavement.

RDEA, p.26

As shown below, providing sufficient runway length to allow category B-II critical aircraft that currently use ARB to operate without load restrictions is not a valid need without providing additional information. Further, lengthening Runway 6/24 is not necessary to achieve the remaining three benefits. Those benefits could be achieved by simply shifting Runway 6/24 150 feet to the southwest, *i.e.*, removing 150 feet from the approach end of Runway 24 and adding 150 feet to the departure end of Runway 24. Runway length would remain 3,505 feet.

This RDEA does not fully evaluate the 150-foot shift alone as a potential alternative to resolving all of the issues that ARB is facing, as noted in § 2.1.4 of the RDEA. The rationale provided for not fully considering this alternative is that ". . . it does not meet the purpose of providing an overall safe, efficient and useable facility at ARB, it does not meet the need to allow the majority of critical aircraft to safely operate at their design capabilities, it does not satisfy the FAA design objectives for the critical aircraft at the airport, and it does not achieve full compliance with the basic development standards outlined in the MASP 2008 for category B-II airports." RDEA, Page 29, Paragraph 3).

However, with regard to safety, (1) the 150-foot shift would resolve any ATCT line-of sight issues with respect to Runway 24, and any prospective problems with local runway overrun issues; (2) there is no evidence provided in the RDEA that the "majority" of critical aircraft cannot already operate safely to their design capabilities at the present airport; (3) FAA design objectives for the airport are based only on an Advisory Circular and are not a matter of law or formal FAA rule and are not part of the "Need;" and (4) the MASP is arbitrary and capricious in its application to ARB, not having been independently evaluated in terms of potential risks.

Further, because the issues of Purpose and Need have been challenged above as not being satisfied, and the legitimacy of the 500-operations have been questioned over multiple years, it is not established that current users of ARB have an established economic need for an expanded airport. There are established arguments to be "proactive in enhancing safety" for not expanding the primary runway at ARB, and for limiting any runway project to the proposed 150-foot shift, which was not fully explored as an alternative (RDEA, § 2.1.4). That alternative should be fully explored, which could lead to it being a preferred alternative resolving all pertinent safety issues. Meanwhile, the current preferred alternative must not be pursued until this 150-foot shift can be fully and properly considered as an alternative.

III. THE RDEA DOES NOT ADEQUATELY CONSIDER THE AFFECTED ENVIRONMENT AND THEREFORE IT IS INADEQUATE.

A. Ann Arbor May Have Violated Its Contractual Grant Assurances in not Considering the Interests of Local Communities.

By proceeding with the Project despite strong opposition of Pittsfield and Lodi Townships, ARB is in violation of its federal grant assurances.

As reported in CPCQ's comments on the DEA (Committee for Preserving Community Quality, DEA Comments, 4-19-10, p.12, ¶ 4), both Pittsfield Township, where ARB is located, and neighboring Lodi Township have passed Resolutions, (March 24, 2010, and May 12, 2009, respectively) opposing the proposed runway expansion. Those Resolutions are contained in the current RDEA as Appendices H and J. The Resolutions basically oppose the expansion because of the risks from Canada geese in areas surrounding the airport, low-flying aircraft on the approaching newly expanding runway, and the fact that 99 percent of the based aircraft can operate at their full weight capacity on the existing runway. Further, the Resolutions described the importance of protecting the property rights of their citizens from degradation. MDOT has ignored these Resolutions and proceeded with the Runway expansion despite the opposition of the jurisdiction ARB is located and the jurisdiction adjacent. Not only is this a violation of NEPA, NEPA Regulations and FAA Order 1050.1F, it is also a violation of the City's federal grant assurances, thereby exposing the City to litigation liability and potential loss of all federal funding for ARB.

On April 16, 2012, the Ann Arbor City Council voted to accept a $45,000 federal Airport Improvement Program planning grant as part of this ARB expansion program, with city officials executing Terms and Conditions of Accepting Airport Improvement Program Grants as a condition of that grant. Two such contractual conditions to which city officials agreed as part of those grant assurances require:

> 6. Consistency with Local Plans: The project is reasonably consistent with local plans (existing at the time of submission of this application) of public agencies by the state in which the project is located to plan for the development of the area surrounding the airport.
>
> 7. Consideration of Local Interest: It has given fair consideration to the interests of communities in or near where the project may be located. (FAA Terms and Conditions of Accepting AIP Program Grants.)

Not only would moving forward with the expansion be inconsistent with these grant assurances to which the City is already contractually bound, but it may violate those grant assurances, opening the City of Ann Arbor to potential litigation under 14 C.F.R., Part 16. Further, the City would be required to make further assurances as part of gaining further millions of dollars in federal AIP funds to move forward with any proposed expansion under the current proposal.

This is even before the manifest conflicts that exist between the communities over airport expansion are examined. It is curious, for example, that Ann Arbor is purchasing greenbelt space and other farmland outside the city throughout Washtenaw County as part of its environmental preservation program. At the same time, the city proposes to destroy natural spaces by expanding a runway unnecessarily in neighboring Pittsfield Township in opposition to its neighbors' wishes, reflecting insensitivity to its next-door community in the process. Such a move of destroying greenspace may be inconsistent with the spirit of Ann Arbor's own master plan. Plus, given Pittsfield and Lodi's Resolutions of opposition, the expansion is clearly not consistent with the will of those governing bodies. As noted in the section on Purpose and Need, the expansion would benefit a minute number of airport users – at best – for a Need that has not been substantiated, while placing at risk thousands of members of the Pittsfield and Lodi communities with added larger and heavier aircraft, flying much closer to their homes, and at lower altitudes, in an area heavily populated by Canada geese. There is no evidence presented in the RDEA that the consideration of the wishes of these local communities have been weighed and seriously evaluated in the RDEA, let alone to the standard of "fair consideration" required by the grant agreement the City signed. In the eight years since the proposed expansion has been pending, for example, not even one study on the potential safety effects of the expansion on the residents of Pittsfield has been conducted. ARB and MDOT have consistently ignored the interests of communities surrounding ARB.

B. Expanding the Runway Will Result in an Increase in Violations of Pittsfield Township's Noise Ordinance

Pittsfield Township, within which ARB is wholly located, has a long-standing noise ordinance making it unlawful for "any person to create, assist in creating, permit, continue, or permit the continuance of any unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township." Pittsfield Township Noise Ordinance. How the lengthening of the runway and the change in glideslope will affect the enforcement of this ordinance has not been examined, as required by NEPA, NEPA Regulations and FAA Order 1050.1F. Moreover, if the ARB runway were to be expanded to the west, as proposed, and the noise impacts on Pittsfield residents were to change, this ordinance would begin to face demands from citizens for more strenuous enforcement.

Justice Rehnquist, in the landmark case *City of Burbank v. Lockheed Air Terminal Inc.*, 411 U.S. 624 (1973) stated that the legislative history of the 1968 noise control amendment to the Federal Aviation Act, and the subsequent 1972 Noise Control Act, provided for local land use planning as a means of controlling the noise impacts on communities surrounding airports. *Burbank*, 411 U.S. at 643. Justice Rehnquist further noted that the House Committee on Interstate and Foreign Commerce specifically advocated the cooperation of state and local governments in achieving noise control. *Id.* Justice Rehnquist concluded from the legislative history that Congress intended only that the FAA regulate the "source" of noise, specifically the "mechanical and structural aspects of jet and turbine aircraft design." *Id.,* at 650. The statute did not, however, limit the states and local authorities from "enacting every type of measure, which might have the effect of reducing aircraft noise . . ." *Id.,* at 650-651. Justice Rehnquist, thus, suggests that so long as local or state governments do not regulate aircraft noise emissions directly, for example by requiring aircraft to meet certain noise standards or requiring certain technical modifications to jet engine design, they are free to regulate noise for the common benefit.

Therefore, all aircraft flying in and out of ARB are subject to Pittsfield's noise ordinance and fines can be levied on the aircraft owners for operating their aircraft such that they create an "unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township."

C. The RDEA Fails to Properly Consider the Intensity of the Impacts on the Surrounding Community.

NEPA Regulation 40 C.F.R. § 1508.27 requires that the Project be placed in context with the surrounding society so that the Project's impact on the affected region, the affected interests, and the locality can be properly evaluated. The RDEA has failed to adequately address this aspect of the environmental assessment and must do so before the Project can be approved. This aspect of the environmental assessment process is often called "Intensity," and it requires consideration of:

(1) Impacts that may be both beneficial and adverse. A significant effect may exist even if the Federal agency believes that on balance the effect will be beneficial.

TABER LAW GROUP PC

(2) The degree to which the proposed action affects public health or safety.

(4) The degree to which the effects on the quality of the human environment are likely to be highly controversial.

(5) The degree to which the possible effects on the human environment are highly uncertain or involve unique or unknown risks.

….

(10) Whether the action threatens a violation of Federal, State, or **local law** or requirements imposed for the protection of the environment."

40 C.F.R. § 1508.27 (emphasis added). *See also* FAA Order 1050.1F, § 4-3.2, p.4-3.

This is critical because this CFR, the National Environmental Protection Act under which the RDEA was prepared, and the due process clauses of the Fifth and Fourteenth Amendments to the United States Constitutions all provide legal protections to the residents living west of the Ann Arbor Municipal Airport.

The citizens living in areas that surround the airport, part of the human environment feel the airport expansion represents an arbitrary denial of their life, liberty, or property in violation of the Fifth and Fourteenth Amendments. These rights cannot be restricted except for a valid governmental purpose. *Bolling v. Sharpe*, 347 U.S. 497 (1954). Critical is that any decision to move forward on the runway expansion must be made by a neutral decision-maker. *Goldberg v. Kelly*, 397 U.S. 254, 267 (1970). This is important because for four decades, MDOT has shown itself to be an advocate for expansion of the ARB primary runway, and not a neutral party. Typically, when a law or other act of government is challenged as a violation or potential violation of individual liberty under the due process clause, courts balance the importance of the governmental interest and the appropriateness of the government's method of implementation against the resulting infringement of individual rights. In cases where state authorities, such as MDOT, are involved, the United States Supreme Court has held that ". . . we cannot leave to the States the formulation of authoritative . . . remedies designed to protect people from infractions by the States of federally guaranteed rights." *Chapman v. California*, 386 U.S. 18, 22 (1967). Thus, MDOT may be forced to recuse itself from any decision in ARB expansion case, an expansion project which poses significant potential risks to citizens living in neighborhoods surrounding the airport.

As we contend and documented above, this proposed project has a statistically small benefit (.00110), at best, and yet would attract larger and heavier jet aircraft in closer proximity to homes in areas heavily populated with Canada geese, potentially jeopardizing residents in the event of an accident – accidents that the FAA contends are the third most frequent that occur in terms of incidents with hazardous wildlife in aviation. This is even more critical given the proposed flatter approach slope now being proposed. The Purpose and Need have not been substantiated. The risk to public safety may far outweigh any established benefit, which has not been substantiated in the RDEA. Added risks in terms of additional noise and night flights have not been established, but with arrival traffic traveling just 93 feet over rooftops on an expanded runway, it could have a controversial and negative impact on the human environment of citizens in Pittsfield Township, in violation of that township's noise ordinance and in violation of federal law.

IV. THE EXTENSION OF THE RUNWAY WILL CAUSE SIGNIFICANT ENVIRONMENTAL IMPACTS ON THE SURROUNDING COMMUNITIES.

United States federal law states at 49 U.S.C. § 47101(a)(6) that it is "the policy of the United States - - that airport development under this subchapter provide for the protection and enhancement of natural resources and the quality of the environment of the United States." The Project will have a significant impact on the environment not only on the airport, but throughout the surrounding community. Since it is Pittsfield Township's duty and responsibility to protect the environment within its boundaries and protect its citizens from significant environmental impacts, it has serious concerns about the environmental impact the Project will have on the community.

A. The Data Used to Justify the Project Is Not Current.

1. RDEA must update the required correspondence with all federal, state and local agencies.

The RDEA fails to update its required correspondence with other federal, state and local agencies and fails to update its environmental evaluations thereby making the RDEA in violation of NEPA and FAA regulations. ARB last sent out correspondence to federal, state and local agencies in 2009. This is a requirement under NEPA and FAA regulations. Under FAA Order 1050.1F and the National Environmental Protection Act Implementing Instructions for Airport Actions (FAA Order 5050.4B) and the National Environmental Policy Act (42 U.S.C. §§ 4321-4347), applicants for airport improvement program funds are required to provide supporting documentary evidence from interested and affected public agencies. Further, the FAA specifies that elements of Environmental Assessments remain valid for only three years with respect to "the affected environment, environmental impacts, and mitigation" and that evaluating officials must determine the extent to which substantial changes are needed. FAA Order 1050.1F.

Numerous such public agency letters are contained in the RDEA (RDEA, Appendix D) from agencies including the Michigan Department of Natural Resources, the U.S. Department of Interior Fish and Wildlife Service, the Michigan Department of Agriculture, the Michigan Department of Environmental Quality, the U.S. Environmental Protection Agency, the United States Department of Agriculture, the Michigan Department of History, Arts, and Libraries, and the Little Traverse Bay Bands of Odawa Indians. However, all the correspondence is from the years 2009-2010 when the project was first proposed – prior to the first DEA. The RDEA is relying on correspondence from public agencies that is seven to eight years old. Conditions have substantially changed for some or all of these agencies in terms of their evaluation of the proposed alternative in the substantial periods since these letters of evaluation were written.

The FAA agreed with this position, stating in its May, 2016 correspondence with the applicant the need to "update letters from 2009 for preferred alternative (Department of Natural Resources instructions that may have changed)" (Comment No. 111, October 2016, MDOT/City comments in response to FAA questions). MDOT and ARB responded by stating that, "As soon as this draft EA is finalized, the regulatory agencies will be contacted in writing and given the opportunity to review, comment and/or update the instructions" (MDOT and ARB response to Comment No. 111). This is unacceptable. The public has a right to know if the public agencies have changed their evaluation of the Project and have a right to comment on the agencies' evaluations as part of the public comment period. To do otherwise would open the door to premature project approval if conditions have changed. All of these conditions must be re-evaluated and the letters updated to comply with FAA Order 1050.1F before the project can be approved.

2. **RDEA must update its environmental evaluations and reports it used to assess the environmental effects of the alternatives.**

The RDEA must also update its evaluations of the environmental effects the Project will have on the environment. Instead of performing additional tests, processes or modeling, the RDEA makes a desktop survey and states whether the eight- to ten-year old test it performed should still be valid. This is unacceptable and in violation of NEPA, NEPA regulations and FAA Order 1050.1F. Even when the draft EA first came out almost seven years ago, Pittsfield Township had issues about the timeliness of the data presented. The data that the Airport relied upon was almost three years old when it was used in the 2010 draft EA. Moreover, it is the FAA's policy to use timely data instead of data that is stale, like the data used to justify the Project.

For example, new noise modeling should be run to assess noise impacts, since the previous one is now eight years old and the FAA no longer uses the Integrated Noise Model, which was used in the original DEA. Indeed, the "future years" scenario in the original DEA was 2014, which is now three years in the past. Many things have changed in the past eight years that may (or may not) have affected the environment surrounding ARB. ARB has a duty under NEPA to investigate what those changes might be and not assume that nothing has changed.

.

B. The Project Does Not Account for the Noise Impact of the Project on the Surrounding Community.

1. MDOT and ARB have a statutory duty to protect the surrounding community from aviation noise.

As stated above, it is "the policy of the United States - - that aviation facilities be constructed and operated to minimize current and projected noise impact on nearby communities." 49 U.S.C. § 47101(a)(2). Part of the FAA's mission, and therefore MDOT's mission, is to ensure that the communities surrounding airports are not adversely impacted by noise from aircraft at airports. This mission is expressed in 49 U.S.C. § 47101(c), which states that "[i]t is in the public interest to recognize the effects of airport capacity expansion projects on aircraft noise. Efforts to increase capacity through any means can have an impact on surrounding communities. Noncompatible land uses around airports must be reduced and efforts to mitigate noise must be given a high priority." Thus, to the extent that noncompatible land uses around airports cannot be reduced, then the capacity of nearby airports should not be increased or else the FAA and the airport sponsor would be in violation of federal law. ARB and MDOT seem to be aware of the fact that increases in capacity at the airport will affect the noise levels in Pittsfield, because they studiously avoid the topic.

MDOT, as the agent for the FAA, has a statutory duty to protect residents and property owners from the deleterious effects of aircraft noise.

TABER LAW GROUP PC

Federal law clearly establishes the absolute duty of the government to protect both people and property from aircraft noise. "[T]he Congress declares that it is the policy of the United States to promote an environment for all Americans free from noise that jeopardizes their health or welfare." 42 USC § 4901(b). In developing the RDEA, MDOT ignored its statutory and regulatory duty to control and abate "aircraft noise and sonic boom." MDOT's statutory duty to protect people and property on the ground from the deleterious effects of aircraft noise goes beyond its duty under NEPA to determine what it believes to be "significant" or "reportable" under FAA Order 1050.1F. Legally speaking, the MDOT cannot draw the conclusion that a proposed MDOT action that is purportedly not "reportable" under 1050.1F, § 14.5e[6] or that purportedly does not have a "significant impact" under 1050.1F, § 14.3[7], is not subject to review and regulation pursuant to 42 USC § 4901(b), 49 U.S.C. § 40103(b)(2) and 49 U.S.C. § 44715(a)(1)(A). Those statutory obligations require that the lead agency address aircraft noise separate and apart from its duties under NEPA because the lead agency's proposed action will create aircraft noise that will have a deleterious effect on the public health and welfare.

2. ARB and MDOT incorrectly assume that extending the runway will not increase the number of air operations, the fleet mix or other growth-inducing effects of the Project.

When considering an airport project for federal funding, the FAA is required to evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project (40 C.F.R. § 1508.8(b)) as

[6] *See also* 1050.1F B-1.4, p.B-4.

[7] *See also* 1050.1F, Table 4-1, p.4-8

TABER LAW GROUP PC

well as increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). The "growth-inducing effects of [an] airport project appear to be its *raison d'etre*." *California v. U.S. D.O.T.*, 260 F.Supp.2d at 978, citing *City of Davis, supra*, 521 F.2d at 675. Even though the Project is virtually defined by its growth-inducing impacts, ARB and MDOT have ignored this requirement completely – not only in the draft EA, but in the public participation aspects of the Project as well.

Contrary to ARB and MDOT's unsupported assertions in the draft EA (*see e.g.* RDEA, p. 42; Appendix B-1), it is reasonably foreseeable that the fleet mix at ARB will change in favor of a higher percentage of jet operations as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft account for a high percentage of ARB operations. B-II aircraft account for a low percentage of ARB operations. Because of the availability of a longer runway, it is therefore reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer haul business jets often occur in the evening hours due to the longer time duration of their trips. Since one of the stated "benefits" of the Project is to increase interstate commerce, this is not merely an indirect, but also a direct effect, that the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

As indicated above, the runway need not be extended in order for most of ARB's "critical aircraft" to operate at the airport without weight restrictions. For example, the "load restrictions" referenced in the RDEA will apply to the higher category aircraft (jets in the C-I and C-II categories). Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, all of which discourage these aircraft from conducting operations at ARB. A Cessna Citation II (Category B-II), for example, requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and, most days, can operate at unrestricted weight from ARB's existing 3,505-foot runway. A Lear 35 (Category C-I), on the other hand, requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,300 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be less than is currently required. Therefore, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide little or no operational benefit to the Category B-II Citation jet, which the RDEA states is a "critical aircraft." Thus, with the runway extension ARB does not become any more or any less attractive to the operator of the Citation II, but becomes more attractive to the operator of the Lear 35 thereby causing an increase in usage of ARB by the Lear 35, but the same amount of usage by the Citation II.

Even the RDEA admits that there will be an increase in operations. Tucked away in its discussion of "Energy Supply and Natural Resources," the RDEA states that "[d]evelopment of the Preferred Alternative would have the potential to increase the amount of air traffic utilizing ARB, which can potentially result in an increase in the amount of airplane fuel distributed by the airport and used by aircraft at the facility." RDEA, p.67. Because there is a potential of an increase in the number of operations, it must be analyzed thoroughly.

The primary reason why ARB is so keen on extending the runway is to facilitate the loading of additional passengers and baggage on high performance jet aircraft outside of what ARB considers to be its "critical aircraft." Also, the ability to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. If the runway is lengthened to 4,300 feet, it is reasonably foreseeable that ARB will become much more attractive to operators of higher performance jet aircraft, such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II), who could then operate at ARB instead of driving to and from Willow Run Airport, a mere 12.3 mile car trip, where there are ample facilities for large aircraft.

TABER LAW GROUP PC

The evidence is clear that the Project will cause an increase in both jet and night operations. It is also reasonably foreseeable that these added high-performance jet aircraft operations and night operations will be accompanied by significant noise and air quality impacts. Nevertheless, ARB and MDOT have failed to acknowledge, let alone analyze, these reasonably foreseeable impacts caused by expansion of airport physical facilities and operational profile and, thus, the Project should not be approved for federal funding.

3. Increased jet aircraft and nighttime operations were not included in the noise modeling used by ARB and MDOT.

The only noise modeling done for the RDEA was performed in 2009. The RDEA claims to have "re-evaluated" the 2009 results and claims that they still apply. On its face, its "re-evaluation" is insufficient to meet FAA standards. The FAA's Integrated Noise Model (INM) was used to model annual operations for the 2009 existing condition in the draft EA, *i.e.*, April 2008 through March 2009 and develop 65, 70 and 75 DNL noise contours for the Project. RDEA, p.41, Appendix B-1. The RDEA states that "[t]his 65 DNL contour does not extend beyond airport property." RDEA, p. 41. However, during the time period modeled, jet operations accounted for approximately 2 percent of total operations at ARB, and nighttime operations accounted for 4.2 percent of total operations. RDEA, p. 41. The draft EA states: (1) "[t]he percent of night and jet operations would remain constant between the existing condition and the future years;" (2) "fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives would remain static"; and (3) "[t]he ARB 2014 proposed project alternative DNL 65 dBA noise contour does not extend beyond airport property." RDEA, p. 40; Appendix B-1. Since the time that the original DEA was published, the FAA now requires the use of the Aviation Environmental Design Tool (AEDT) for noise modeling instead of the Integrated Noise Model (INM). Because of the change in models, the RDEA must use AEDT to produce the noise modeling for ARB.

None of these assertions are based on facts or the reality of the situation that exists at ARB. As shown above, because of the increase in the length of the runway the Project will likely facilitate an increased number of night operations, and a change in fleet mix that will include higher performance jet aircraft. DNL calculations depend on, among other things, forecast numbers of operations, operational fleet mix and times of operation (day versus night). RDEA, Appendix B-2. However, ARB and MDOT have failed to model or assess future increased night operations and fleet mix changes resulting from the Project.

Thus, ARB must use AEDT to produce among other things: (1) noise contours at the DNL 75 dB, DNL 70 dB and DNL 65 dB levels; (2) analysis within the proposed alternative DNL 65 dB contour to identify noise sensitive areas where noise will increase by DNL 1.5 dB ; and (3) analysis within the DNL 60-65 dB contours to identify noise sensitive areas where noise will increase by DNL 3dB, if DNL 1.5 dB increases as documented within the DNL 65 dB contour. FAA Order 1050.1F. As the noise modeling failed to account for the foreseeable increases in nighttime and jet aircraft operations at ARB, the questions of whether the future DNL 65 dB contour will be increased, and to what extent, and whether increased noise levels within the DNL 65 dB contour would necessitate designation of a DNL 60 dB contour remain unanswered.

4. Noise from aircraft, particularly high performance jets, remains a very real concern for communities that surround ARB.

The FAA last reviewed the technical bases for its noise policies in 1992. For example, 65 DNL as the "threshold of significant impact" under NEPA and the level below which land uses are deemed compatible has been used by the FAA without substantial change since *1978* (it was "re-affirmed" by FICAN in 1992). It is safe to say that the FAA's policy no longer reflects the best scientific evidence of the effects of aircraft noise exposure. This failure on the part of the FAA to update its policy undermines the trust that the public places in the FAA in their pursuit to understand noise exposure and its effects.

This is particularly true since substantial research done on the measurement and effect of aircraft noise on the communities surrounding airports has come from sources outside the United States. For example, the Hypertension & Exposure to Noise Near Airports (HYENA) study evaluated the effects of aircraft noise on 4,861 persons residing near 7 European airports between 2002 and 2006. The 2002 RANCH study from London studied the effect of aircraft and road traffic noise on 2,844 children's cognition and health. Both of these studies came out with rather startling results concerning the effect aircraft noise has on the quality of human life. Finally, WHO Europe issued "Night Noise Guidelines," which were based on research done by the European Union. This type of study has largely been absent in the United States.

The emerging research suggests that current standards used by the FAA are outdated and underestimate the significant health risks posed by aircraft noise. The current understanding of the health effects of aircraft noise goes beyond mere annoyance and sleep disturbance, which the current DNL protocols were meant to address. The new research shows a strong correlation between aircraft noise and significant, serious health outcomes, such as hypertension and heart disease. Four studies from Europe have shown this connection:

1. Haralabidis AS, Dimakopoulou K, Velonaki V, Barbaglia G, Mussin M, Giampaolo M, Selander J, Pershagen G, Dudley ML, Babisch W, Swart W, Katsouyanni K, Järup L; for the HYENA Consortium. Can exposure to noise affect the 24 h blood pressure profile? Results from the HYENA study. *J Epidemiol Community Health*. 2010 Jun 27.

2. Haralabidis AS, Dimakopoulou K, Vigna-Taglianti F, Giampaolo M, Borgini A, Dudley ML, Pershagen G, Bluhm G, Houthuijs D, Babisch W, Velonakis M, Katsouyanni K, Jarup L; for

4. Jarup L, Dudley ML, Babisch W, Houthuijs D, Swart W, Pershagen G, Bluhm G, Katsouyanni K, Velonakis M, Cadum E, Vigna-Taglianti F for the HYENA Consortium. Hypertension and exposure to noise near airports (HYENA) - Study design and noise exposure assessment. *Environ Health Perspect* 2005; 113:1473-8.

This is not to say that there has not been any research done in the United States on this issue. In March 2007, for example, Lisa Goines and Louis Hagler published their article entitled "Noise Pollution: A Modern Plague" in the *Southern Medical Journal*. While it did not concentrate solely on aircraft noise, the article concluded that

> [n]oise produces direct and cumulative adverse effects that impair health and that degrade residential, social, working, and learning environments with corresponding real (economic) and intangible (well-being) losses. It interferes with sleep, concentration, communication, and recreation. The aim of enlightened governmental controls should be to protect citizens from the adverse effects of airborne pollution, including those produced by noise. People have the right to choose the nature of their acoustical environment; it should not be imposed by others.

ARB and MDOT are imposing the nature of their "acoustical environment" on Pittsfield and its citizens, rather than having the citizens choosing for themselves.

In addition, several "findings" have been issued by governmental or quasi-governmental sources. The Federal Interagency Committee on Aviation Noise (FICAN) has issued two findings: *FICAN Recommendation for use of ANSI Standard to Predict Awakenings from Aircraft Noise* (2008) and *Findings of the FICAN Pilot Study on the Relationship between Aircraft Noise Reduction and Changes in Standardized Test Scores* (2007). Partnership for AiR Transportation Noise and Emissions Reduction (PARTNER), a collaboration among the FAA, NASA and TransportCanada, issued in July 2010, its *Review of the Literature Related to Potential Health Effects of Aircraft Noise*, (prepared by Hales Swift). That review concluded that "[p]otentially serious health outcomes have been identified in studies involving transportation noise exposure in a population. These include heart disease and hypertension and the observed effects seem to be related especially to nighttime noise exposure although similar daytime exposure effects have also been identified." PARTNER 2010, p.62. PARTNER has also issued several other reports:

• Sonic Boom and Subsonic Aircraft Noise Outdoor Simulation Design Study. Victor W. Sparrow, Steven L. Garrett. A PARTNER Project 24 report. May 2010. Report No. PARTNER-COE-2010-002.

• Passive Sound Insulation: PARTNER Project 1.5 Report. Daniel H. Robinson, Robert J. Bernhard, Luc G. Mongeau. January 2008. Report No. PARTNER-COE-2008-003.

• Vibration and Rattle Mitigation: PARTNER Project 1.6 Report. Daniel H. Robinson, Robert J. Bernhard, Luc G. Mongeau. January 2008. Report No. PARTNER-COE-2008-004.

• Low Frequency Noise Study. Kathleen Hodgdon, Anthony Atchley, Robert Bernhard. April 2007. (Report No. PARTNER-COE-2007-001) PARTNER Project 1, Low Frequency Noise Study, final report.

• Land Use Management and Airport Controls: A further study of trends and indicators of incompatible land use. Kai Ming Li, Gary Eiff. September 2008. Report No. PARTNER-COE-2008-006

• En Route Traffic Optimization to Reduce Environmental Impact: PARTNER Project 5 Report. John-Paul Clarke, Marcus Lowther, Liling Ren, William Singhose, Senay Solak, Adan Vela, Lawrence Wong. July 2008. Report no. PARTNER-COE-2008-005

• Land Use Management and Airport Controls: Trends and indicators of incompatible land use. Kai Ming Li, Gary Eiff, John Laffitte, Dwayne McDaniel. December 2007. (Report No. PARTNER-COE-2008-001) PARTNER Project 6 final report.

Thus, there is no shortage of relevant, topical information for ARB to use in assessing the health risks and impacts of noise on the communities surrounding ARB. It is readily apparent that the current system does not fully account for the increased health risks communities surrounding airports are subject to due to the increased noise levels. ARB needs to re-evaluate its noise modeling and insist that health risks to the surrounding communities be assessed prior to ARB receiving federal funds for any expansion that will result in an increase in aviation operations.

C. Air Quality: The RDEA Fails to Take Into Account the Effects the Project Will Have on Air Pollution in the Surrounding Community.

Section 7506 of the Federal Clean Air Act (42 U.S.C. § 7401 et seq.) mandates that "[n]o department, agency, or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to [a State Implementation Plan] after it has been approved or promulgated under [42 U.S.C. §7410]." The Environmental Protection Agency (EPA) has promulgated regulations implementing § 7506 (the "Conformity Provision") in 40 C.F.R. § 93.150 *et seq.* ("General Conformity Rule"). The General Conformity Rule requires, in part, that federal agencies first determine if a project is either exempt from conformity analysis or presumed to conform. If it is neither, the agency must conduct a conformity applicability analysis to determine if a full conformity determination is required. *See Air Quality Procedures for Civilian Airports and Air Force Bases*, p. 13.

The project area, *i.e.*, Washtenaw County, is in attainment for five of the eight criteria pollutants, and maintenance for Ozone, PM_{10} and $PM_{2.5}$. Exhibit 2. A conformity determination is required for criteria pollutants in maintenance areas. 40 C.F.R. § 93.153(b). Therefore, one of the following applies:(1) the project is exempt from conformity; (2) the project is presumed to conform; or (3) the agency must conduct a conformity applicability analysis to determine if a conformity determination for Ozone, PM10 and $PM_{2.5}$ is required. ARB has not indicated that any of the required actions has been performed even though required by NEPA and FAA Order 1050.1F. The RDEA does not provide any guidance as to whether the Project is exempt or presumed to conform

1. The RDEA fails to establish that the Project is exempt.

There are two options in determining that a project is exempt from conformity analysis: (1) if the project is included in the list of exempt actions listed in § 93.153(c)(2); or (2) if the project's total of direct and indirect emissions are below the emissions levels specified in § 95.153(b) of the Conformity Regulations ("*de minimis*"), § 93.153(c)(1).

The first option does not apply here because none of the actions to be undertaken as part of the Project are included as "exempt actions" §

93.153(c)(2). Nor does the Project qualify as exempt because of *de minimis* emissions under 40 C.F.R. § 93.153(c)(1) because no air quality analysis was performed. The RDEA assumes that because Washtenaw County is no longer in non-attainment for a particular criteria pollutant, it is not required to perform an air quality analysis. This assumption, however, does not comply with federal law for at least two reasons. First, the RDEA does not quantify Ozone, PM_{10} and $PM_{2.5}$ emissions from flight operations at ARB. Second, because the RDEA fails to quantify the emissions, there can be no comparison with the *de minimis* thresholds established in 40 C.F.R. § 93.153(c)(1).

2. The RDEA fails to establish that the project is "presumed to conform."

The second option, the presumption of conformity, does not apply here either. In order for a federal action to be "presumed to conform," the Project has to fall within a category of actions predetermined by the responsible federal agency to carry a presumption of conformity. *See* 40 C.F.R. § 93.154(f) – (h). In July, 2007, the FAA published its *Federal Presumed to Conform Actions Under General Conformity Final Notice*, 72 Fed.Reg. 41,565-580 (July 2007), in which the FAA listed fifteen Airport Project categories that the FAA presumes to conform to applicable SIPs. None of the actions to be undertaken by the Project fall within any of those presumed to conform categories. The RDEA cannot unilaterally presume that the Project is in conformity.

3. The RDEA fails to establish the Project's conformity status under the Clean Air Act.

Finally, 40 C.F.R. § 93.159 requires that analyses under the General Conformity Rule be based on, among other things: (1) "the latest planning assumptions" (§ 93.159(a)); and (2) "the latest and most accurate emissions estimation techniques available" (§ 93.159(b)) none of which are covered in the RDEA.

TABER LAW GROUP PC

D. The RDEA Fails to Take Into Account the Effect the Project Will Have on Water Resources in the Surrounding Communities.

The RDEA consistently understates the significance of the effect that the Project will have on water resources and water quality. The principal and longest use of the grounds where the airport is located has been for the collection and pumping of water for the City.[8] Before the first aircraft landed on the property of what is now ARB, Ann Arbor was using the property to supply its drinking water.[9] However, the RDEA fails to take water quality seriously. As FAA Order 1050.1F points out "[i]f there is the potential for contamination of an aquifer designated by the [EPA] as a *sole or principal drinking water resource* for the area, the responsible FAA official needs to consult with the EPA regional office, as required by section 1424(e) of the Safe Drinking Water Act, as amended." FAA Order 1050.1F, p.4-12 (emphasis added). Likewise, "[w]hen the thresholds indicate that the potential exists for significant water quality impacts, additional analysis in consultation with State or Federal agencies responsible for protecting water quality will be necessary. *Id.*, pp. A-75, A-76, & 17.4a. Finally, in situations such as this, "[i]f the EA and early consultation [with the EPA] show that there is a potential for exceeding water quality standards [or] identify water quality problems that cannot be avoided or mitigated . . . an EIS may be required." *Id.*, pp. A-75, & 17.3. Based on these requirements, the RDEA is inadequate. As expressed in NEPA, the NEPA Regulations, and FAA Order 1050.1F, drinking water

---

[8] The land where that grass runway now exists was purchased by Ann Arbor in 1921, seven years prior to the first aircraft landing, when the Steere Water Farm was acquired for water rights, not aviation. The purpose was to sink wells to support the growing city's drinking water needs.

[9] In fact, Ann Arbor attempted to annex the airport grounds in 1976, but that annexation was ruled illegal and vacated by the court (Charter Township of Pittsfield v. City of Ann Arbor, Washtenaw County Circuit Court, Judge Campbell, 77-12619-CZ, 12-22-76, Summary Judgment) later that year.

contamination is too important of an issue to rely on outdated reports that are based on conjecture instead of data.

The Airport is the location of a porous sand/gravel formation that yields a large amount of water for pumping. Historically, the land where the airport is located was originally acquired by the City of Ann Arbor for water rights in 1921. Until recently, 15% of Ann Arbor's water supply came from the three wells located on Airport property. Exhibit 3, Water Quality Report, 2015, City of Ann Arbor, p.2. The paving that the Project will require increases not only the impervious area on top of the aquifer, but also increases the risk of contamination. This in turn reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer that is vital to the City. However, the RDEA gives this issue only passing mention: "[b]ased on coordination with the City of Ann Arbor, the proposed runway extension would not impact the water supply wells or the new water supply line (Bahl, 2009)." RDEA, p.60. Notably absent from their coordination efforts is the EPA, its Regional Office, the Michigan Department of Environmental Quality, and Washtenaw County with respect to water quality issues.

So critical is drinking water from the airport wells to the city that de-icing is prohibited on the airport. And despite the claim in response to comments to the 2010 DEA (RDEA, Appendix K, Page 2, Paragraph 1) that, "drainage from airport pavements sheet flows through hundreds of feet of vegetation before infiltrating. Due to the 'unmaintained nature' of the airport vegetation, it is acting as a buffer around the wellheads," the water faces many potential threats from a lengthened runway. Those threats become more critical because of how lead contaminated the water supply in nearby Flint. This is relevant here because the majority of fuel utilized at ARB is consumed by piston-driven aircraft, which mostly use leaded AvGas. Any risk to the aquifer underlying the airport could pose a lead threat, which is in addition to the potential dioxane risks to Ann Arbor's only other drinking water source on the Huron River because of nearby contamination that has not been fully resolved, locally referred to as the "Gelman spill." The RDEA further claims that the airport wells are within a "wellhead protection zone" and that Ann Arbor's Water Treatment Plant Manager "indicated the preferred alternative will not result in adverse impact to the wellhead protection area" (RDEA, Appendix K, Response 81, Paragraph 2.) However, that report, like others based on expert sources, was based on 2009 information, and only speculation – not any actual testing.

Because the wells on ARB property is a principal source of Ann Arbor's water supply, the Washtenaw County Water Resources Commissioner – another entity with whom ARB and MDOT should have been consulting from the very beginning – raised serious issues about the Project. In response to the draft EA, the Washtenaw County Water Resources Commissioner pointed out:

> It is noted in the [draft EA] that: "The amount of impervious surface on site would increase slightly due to the extension of the runway and taxiway from the existing 7 percent of the 837 acres to 7.4 percent." This slight increase noted equates to an additional 3.348 acres or 145,839 square feet. This increase in impervious surface is considered by this office to be significant and not slight particularly knowing that the additional runoff from this area will discharge to the Wood Outlet Drain.

RDEA, Appendix K. This, coupled with the fact that the City owns four and operates three water wells on ARB's property, causes deep concern with the County.

This issue has become even more important since the draft EA was published back in 2010. In May, 2012, it was reported that the water table in the Ann Arbor area, has risen substantially. As pointed out in the Ann Arbor Chronicle, "[t]he only hard data that the city has collected on the water table is at the municipal airport, and there the water table measures between 2-7 feet below the surface now, compared to 15 feet below the surface 50 years ago."

Exhibit 4.[10] This is not an insubstantial problem. With the water table at the airport now being 2-7 feet below the ground surface instead of 15 feet, when the drinking water wells were first dug, the groundwater is even more vulnerable to contamination because there is much less soil for any surface pollution to filter through or attach to soil particles before it reaches the water table. This dramatic change in the water table may also alter ground water data from the past. That is, the rise in the water table may have altered the direction of groundwater flow, or there may now be some barrier blocking the traditional pathway for the water to flow, which would cause Ann Arbor's principal drinking water supply to be contaminated.

The Washtenaw County Water Resources Commissioner raised additional significant concerns that have yet to be addressed by either ARB or MDOT.

3. It is indicated that the preferred alternative does not impact the stream that is existing on the site. [Draft EA, p.4-18]. Using GIS measurements it appears that the stream is less than 1,000 linear feet from the existing runway. The runway extension would bring this infrastructure within 50 linear feet or less of the stream. In addition to this the grading limits shown in Appendix D-7 clearly extend into and beyond the location of the stream. Based on this information *it is not understood how it has been concluded that there are no impacts to the stream*.

4. It is indicated that the preferred alternative does not impact the floodplain for the stream that is existing on the site. It is indicated that proposed grading for the expansion would not occur within the designated floodplain boundary. [Draft EA, p.4-24]. Based on the floodplain boundary shown on FEMA Community-Panel Number: 260623 0010 C these statements are incorrect. Not only do the grading limits indicated for the preferred alternative extend into the floodplain boundary but

---

.[10] By contrast, the draft EA relies on data at least 15 years old. Since there is more current data, that should be used instead of outdated data. *See* RDEA, pp.59-60.

> the runway extension itself will extend into this floodplain boundary. Based on this information it is *not understood how it has been concluded that there are no impacts to the floodplain*.
>
> ….
>
> 6. It is noted in the report that: "Implementation of appropriate best management practices (BMPs) would continue to control the rate of stormwater runoff and maintain water quality standards." [Draft EA, p.4-18]. It is unknown by this office as to what the control rate of stormwater is currently being implemented or whether this rate meets county standards. *The additional volume created by this increase in imperviousness is not spoken to at all by the report. The type or locations of the appropriate BMPs indicated are not identified.*

RDEA, Appendix K (emphasis added). Pittsfield Township has the same concerns about how water resources will be managed by ARB should this Project move forward. These issues have not been sufficiently addressed by the RDEA.

ARB has a responsibility under this law to ensure the safety of the water in Ann Arbor's wells. Further, although Pittsfield Township does not receive its drinking water from these wells, water from the same aquifer filling these wells is the source of water for numerous Pittsfield Township waterways, including the several ponds in the Stonebridge Community. Thus, beyond ensuring applicant Ann Arbor's compliance with the law, Pittsfield Township and CPCQ have a vested interest in ensuring the water in the aquifer be maintained to the highest possible quality level.

This project should not be approved by MDOT until these requirements regarding water quality have been complied with fully.

TABER LAW GROUP PC

E. Wildlife Hazards Remain Undetermined.

1. Risk of Canada Geese strikes requires Wildlife Hazard Assessment before any further AIP grants may be awarded to ARB.

The RDEA responds to comments to the 2010 DEA regarding risks because of large numbers of Canada geese surrounding ARB, which become a greater risk because the larger number of jets that would be attracted to a lengthened runway, because such jets travel at higher speeds than traditional piston-driven aircraft. Our comments to the 2010 DEA raised the risk of the large number of Canada geese and provided photographic evidence to support the claim (Committee for Preserving Community Quality, 4-19-10, pp. 9-10, and Exhibit 3 photographs). However, the response to those numerous comments in the current RDEA (RDEA, Appendix K, Page 1) state that, "…MDOT staff has been monitoring the Stonebridge ponds and farm field along Lohr Road since the project was initiated in the spring of 2009. Groups of geese (less than 10 total) have been observed at various times in and around Stonebridge ponds. No geese have been observed in the farm field east of Lohr Road by MDOT during this time. Based on these observations and those from airport staff, there has been no indication hazardous wildlife conditions exist on or in the immediate vicinity of ARB.

"However, during the course of the public comment period Ann Arbor Municipal Airport (ARB) has received numerous letters alleging significant populations of geese in the Lohr Road farm field and the Stonebridge ponds. If these allegations are true, these populations are within 5,000 feet of the existing runway end and therefore, would be considered an existing hazardous wildlife situation.

"Relocating the runway end would neither increase nor decrease the potential for adverse wildlife interaction since the approach is already over these areas (92% of strikes occur at less than 3,000 feet above ground level, FAA). Therefore, ARB will consider this issue independently from the proposed runway project and will retain the services of a qualified wildlife biologist to perform a Wildlife Hazard Assessment and provide recommendations" (Paragraphs 5-8). This is unacceptable and contrary to federal law.

Applicant Ann Arbor had provided these same responses in submissions to the FAA three years earlier in 2014 received under the Freedom of Information Act (FAA FOIA No. 2016-003646GL), but in the ensuing years – based on no updates or changes in the content of the current 2017 RDEA – ARB has apparently done nothing to retain the wildlife biologist discussed and conduct the Wildlife Hazard Assessment it committed to doing. However, the RDEA reports (RDEA, Page 65, Paragraph 2) that an endangered species specialist has confirmed that "no new species are reported and the original data were substantially valid" from eight years ago. The fact that Canada geese are not endangered and that this assessment was conducted by an "endangered species specialist" rather than as a broader Wildlife Hazard Assessment could well have been because significant Canada geese were discovered as part of that assessment. Given that, attached as exhibits are recent photographs of substantial Canada geese on or near airport flyways and on Stonebridge ponds (Exhibits 5 and 6) in Fall 2016, and on the farm field west of the airport (Exhibit 7).

FAA Advisory Circular 150/5200-33B discusses Hazardous and Protected Wildlife Attractants on or Near Airports and ranks geese as No. 3 in causing damage to aircraft. It discusses how golf courses, such as the one within 1,500 feet of the proposed expanded runway end, are particularly attractive to Canada geese. This alone, with the two large ponds at Stonebridge, is one reason for the continued sightings of large numbers of Canada geese on the flightpaths of ARB. And the potential risks that these Canada geese could cause, especially if large numbers of jets are attracted to a lengthened runway at ARB, underscore the urgency of conducting such a Wildlife Hazard Assessment before this project can proceed. Moreover, the lengthened runway will put the aircraft lower and closer to the areas where Canada geese congregate. To make matters worse, by changing the glideslope from the current 20:1 slope to a 34:1 slope, aircraft on approach to ARB will be exposed to the Canada Geese flyways for a longer period of time thereby increasing the risk of a bird strike.

Further, the Migratory Bird Act of 1918 (16 U.S.C. § 703-712) makes it illegal to kill a Canada goose or harm their nests or eggs. So not only do Canada geese pose a potential risk of causing an aviation accident, but they are also protected, causing what should be a dual concern to the applicant. This is compounded by the fact that mute swans, a species even larger than Canada geese, also inhabit the Stonebridge area just west of ARB, and could pose a further accident risk. As a result, a Wildlife Hazard Assessment must be completed before the proposed runway expansion project can move forward.

2. Presence of Canada Geese pose safety risks and mandates further study prior to lengthening runway.

The documented risk from Canada geese requires applicant Ann Arbor to conduct an immediate Wildlife Hazard Management Assessment (14 C.F.R. § 139.337(b)(4)), which specifies that such an assessment must be conducted *immediately* when any of the following events occurs on or near the airport:

> (4) Wildlife of a size, or in numbers, capable of causing an event described in paragraphs (b)(1), (b)(2), or (b)(3) of this section is observed to have access to any airport flight pattern or aircraft flight pattern or aircraft movement area.

14 C.F.R. § 139.337(b)(4). The "events described in paragraphs (b)(1) – (3)" are wildlife strikes, engine ingestion of wildlife, and/or substantial damage to aircraft from striking wildlife.

Even the up to 10 Canada geese sighted that applicant Ann Arbor stipulated to in Appendix K, Page 1, would be sufficient to warrant such incidents and, hence, such a Wildlife Hazard Assessment. And the fact that the applicant did not undertake such a study on its own, as it committed to doing, since the issue was first recognized and discussed in the draft of this

RDEA submitted to the FAA in 2014, but only an updated endangered species assessment, is sufficient evidence that the Wildlife Hazard Management Assessment must be mandated to be completed and acted upon before any further federal AIP fund grants can be awarded to the applicant. Further, that completed Wildlife Hazard Management Assessment must be submitted to, evaluated, and approved by the FAA administrator before any further action on the proposed project can proceed. 14 C.F.R. § 139.337(e)(2).

V. SAFETY ISSUES DO NOT JUSTIFY RUNWAY EXPANSION AND INCREASE DANGERS TO SURROUNDING COMMUNITIES.

The RDEA frequently emphasizes the issue of safety, but only with regard to the airport, its airplanes, and their fliers -- not once in the 428-page document is there a single reference to the concern for the safety of citizens in the communities surrounding the airport. This is especially troublesome given two recent small jet crashes nearby – one on a runway comparable to that proposed for an expanded ARB, a crash which could have been catastrophic had it occurred here.

A. Runway Overruns Do Not Justify Runway Expansion, But Related Runway Excursions Could Be Deadly.

The RDEA further describes a goal of reducing runway overruns, claiming 11 such previous such overruns by smaller category A-1 aircraft (RDEA Section 1.8.3). The RDEA states that curbing overrun incidents is a goal of the Project, concluding, "[t]here is no evidence in the incident reports that any of the aircraft which overran the end of the existing 3,505-foot runway exceeded the limits of the 300-foot-long turf Runway Safety Area (RSA). Therefore, in each of these cases, the proposed 4,300-foot runway would have provided sufficient length for the small category A-1 aircraft to safely come to a stop while still on the runway pavement, without running off the runway end." RDEA, p.25. However, our review of the 11 runway overrun incidents shows they were all the result of pilot error or mechanical problems – one as careless as the lack of marking construction areas on the runway itself by the airport operator, so the pilot was unaware of a construction berm. The FAA agreed that these incidents did not support runway expansion, concluding in its comments to the 2010 DEA, "…[t]he local objective of reducing runway overrun incidents appears to conclude that if the added runway length were present, all the incidents would have been avoided. Based on the information presented, the FAA does not necessarily come to the same conclusion. There are many factors that go into any overrun incident and if additional runway length were present this may have only prolonged the overrun incident. The A-1 category of aircraft involved with the overrun incidents do not appear to have needed any length beyond the existing runway length to operate at full capacity and in a safe manner." RDEA, Appendix J, FAA letter dated 5-13-10, pp. 5-6, ¶¶ 7 (p.5) and (p.6).

While the RDEA raises the issue of overruns to support expanding the runway erroneously, there is evidence that expanding the runway could lead to *additional* runway excursions. This is a result of the potential dangers created by attracting more business jets because of the extended runway length. On February 11, 2016, the National Business Aviation Association reported that runway excursions by business jets on landings cause about one-third of all runway excursions, making them the most common business aviation accident, occurring about twice weekly somewhere in the world at a cost of about $900 million annually. These incidents are frequently caused by not aborting landings when pilots should, landing at unfamiliar airports, and landing too fast and too far down the runway. The added risk for ARB is that these larger jet aircraft, with larger fuel payloads, could pose added challenges to firefighters in the event of an emergency. Those firefighters are not based on the ARB airport, which does not actually provide on-site fire and rescue services – and are provided by Pittsfield Township. These risks have not been considered or evaluated in this RDEA.

One such excursion occurred quite recently -- just 20 miles northwest of Ann Arbor on January 16, 2017, at the Livingston County Spencer J. Hardy Airport (OZW) in Howell, when just such an unfamiliar pilot attempted to land his Cessna Citation 525 CJ4, but crashed on landing, destroying the aircraft and injuring the pilot, with a broken back. The pilot, who was the only one aboard the 10-passenger, twin-engine jet, apparently lost control on landing, skidding off the end of the runway, through a fence, across a road, and striking a clump of trees, tearing the wings from the fuselage, and causing a fire. Witnesses helped the pilot from the wreckage before emergency crews could arrive (L.T. Hansen, "Report: Plane with single occupant crash-lands at Livingston County Airport," *MLive.com*). The distance from the end of the runway to the trees is about 1,800 feet.

This is important because while the Livingston County airport runway is 5,000-feet long – 700 feet longer than the proposed ARB extended runway – the aircraft would have been more than capable of landing on an expanded ARB runway of 4,300-feet. And, as discussed below, the Runway Safety Zones (RSZs) and Runway Protection Zones (RPZs) frequently mentioned by MDOT as protecting neighborhoods surrounding airports from the effects from potential aircraft accidents, afforded no such benefits in this case. In fact, if a similar incident were to have occurred at an expanded ARB, with a high-speed jet crashing, skidding not just 1,800 feet, but 2,500 feet – because the Livingston County airport runway was longer -- beyond the end of an expanded 4,300-foot ARB runway, and burning, it could have ended up in homes across Lohr Road from the end of the runway, which could have been deadly!

These same type of Cessna jets have crashed on takeoff into two Great Lakes – an organ transplant team from the University of Michigan departing from Milwaukee about a decade ago (into Lake Michigan), killing six, and a family returning from a Cleveland Cavaliers basketball game that crashed on takeoff, killing all six on board (into Lake Erie) last December. The National Transportation Safety Board (NTSB) released a preliminary report on the Cleveland crash in January 2017, reporting that the owner-pilot of the Cessna Citation CJ4 had only been certified to operate the aircraft for three weeks ("NTSB Posts Preliminary Report on Cleveland CJ Crash," R. Mark, *Flying,* 24 January 2017). The report shows the aircraft turned right after takeoff, climbed to an altitude about 1,000 feet higher than assigned, then entered a descending right turn before crashing two minutes after takeoff, less than two miles from the airport, into the lake.

The NTSB has reported on the significant danger of crashes in private and charter airplanes vs. commercial aircraft, the type of aircraft likely to be attracted to an expanded ARB. Between 2000 and 2015, the NTSB found there were five times more fatal accidents in the U.S. involving private and chartered corporate planes than airlines. Investigators cited pilot error in 88 percent of the crashes, noting crews skipping safety checks, working long days, missing rest periods, overlooking ice on wings, or trying to land when they could not see the runway as among the causes of crashes ("Private Jets Have More Fatal Accidents than Commercial Planes," A. Levin, May 15, 2015, *Bloomberg News*).

"I was constantly hearing stories of corporate pilots who don't get enough rest or who are always concerned about being pressured to press on," Stuart Matthews, former president of the Flight Safety Foundation, told Bloomberg News.

Between 2000 and 2015, there were 62 reported fatal accidents involving the most sophisticated models of corporate-style jets and turboprops operated by professional pilots, compared with 13 such accidents by passenger airlines, with 107 fatalities since 2007 in the private-charter crashes compared with 50 deaths in airline crashes.

"Nobody's paying attention," said former NTSB member Kitty Higgins, a board member from 2006 to 2009. NTSB Chairman Christopher Hart added that more regulations would not help: "A lot of times we're talking about people who aren't following the regulations anyway, so I'm not sure that more regulation is the answer" (*Bloomberg News*, May 15, 2015).

And the record may be even worse for hobbyist pilots such as those who crashed in Cleveland and in Livingston County, because their primary occupations are not as pilots, but in doing other things, such as operating their businesses. Such hobbyist pilots may not have sufficient experience and reaction times for high-speed jets when problems develop, especially at airports close to population centers. But even if such pilots are to fly jets, they might be better advised to do so into larger airports – such as Willow Run and Cleveland Hopkins, which provide more operating room and degrees of freedom to recover in emergencies. However, these pilots cannot be kept away from airports close to population centers such as ARB. Consequently, the larger airports were not utilized in the accident cases discussed above, and smaller airports were used – Cleveland Lakefront and Livingston County, possibly exacerbating the accidents that occurred.

In short, the best way for an ARB surrounded by population centers to avoid such potential tragic problems is to not expand the existing airport and invite such larger and heavier jet aircraft to impose such dangers and risks given the small, if any, benefit any expansion would provide. The current airport is safe and presents no such dangers.

B. Changing the Runway Approach Slope Is Unjustified and Creates Additional Safety Issues that Have not Been Considered.

The RDEA proposes, as part of the Project, to flatten the approach slope to ARB's Runway 24 from the current 20:1 slope to 34:1 slope. RDEA, § 1.8.2, p.24, ¶ 6. According to the RDEA, this would provide "an additional margin of safety" from ground based obstacles. The lower, flatter approaches, however, would also expose aircraft to Canada geese for a longer period of time, raising the potential risk of accident, while providing no appreciable benefit. While the RDEA suggests this shift in the slope provides an added margin of safety, it presents a greater margin of risk given the high risk caused by Canada geese that inhabit the wetlands to the east of the airport -- especially given the likelihood of increased jet traffic a lengthened runway would attract. There is no justification for such a slope change established in the RDEA. The risks of such a slope change far outweigh any benefits.

TABER LAW GROUP PC

C. Line-of-Sight Concern Raises Controversial Issue to Justify 150-Foot Runway Shift.

As part of the Project, the RDEA proposes a 150-foot shift of the northeast end of Runway 24 to the southwest to "enhance the safety of ground operations by taxiing aircraft" on Runway 24. RDEA, § 1.8.1. The RDEA goes on to support this recommendation by claiming that two separate buildings currently block the view from the Air Traffic Control Tower (ATCT) to the taxiway hold area on Runway 24. The RDEA reports that the resulting area of restricted visibility has been designated as a "hot spot" by the FAA. Although not an immediate hazard, this situation can "…lead to a confusing condition which may be compounded by miscommunication between a pilot and controller. . ." RDEA, § 1.8.1, ¶ 1. Section 1.8.1 of the RDEA concludes by suggesting that the proposed shift would enhance operational safety, and possibly prevent a runway incursion by expanding the view of the hold area and parallel taxiway to ATCT personnel.

The RDEA goes on to discuss the fact that other alternatives had been considered "initially," but were dismissed as not being reasonable – such as removing and reconstructing the structures, or raising the ATCT, or constructing it elsewhere. But while these details were summarized in the RDEA and in response to an FAA question to the 2010 DEA (RDEA, Appendix K, Response No. 55, ¶ 5), no specific financial estimates were provided. In the end, since any spending will be done with federal Airport Improvement Program dollars, these alternatives must be examined and denominated in dollars, so that the FAA can make the best-informed decision as to both the spending of these funds and the best location of its ATCT. Relatedly, in examining alternatives to the Runway 24 line-of-sight issue, apparently, no alternative as simple as installing a series of cameras was even considered, which could provide sufficient visibility to the Runway 24 hold area for the ATCT. This certainly would be much cheaper and more practical than adding 150 feet of runway.

TABER LAW GROUP PC

Finally, although such a thorough study has not been conducted, this 150-foot shift has been recommended. In responding to questions from the 2010 DEA, ARB states, "[w]hile we are not aware of any incursions that have actually occurred as a result of this condition, we believe it is appropriate to address this condition while the runway condition is being considered . . .**MDOT would rather be proactive in enhancing the safety** of this situation prior to a potentially catastrophic runway incursion taking place, rather than waiting for one to take place and reacting to it afterwards." RDEA, Appendix K, Response 34, ¶¶ 2-4 (emphasis added).

D. MDOT Logic of Being Proactive to Enhance Safety Has Multiple Applications.

Just as MDOT's proactive approach to enhancing safety (mentioned in the above paragraph) may have application to the proposed 150-foot shift in the case of the ATCT, so, too, does that proactive approach apply to the entire proposed runway expansion and the risks it poses to the surrounding community. MDOT wrongly assumes that all aviation accidents related to takeoffs and landings are contained within those areas provided for in FAA Advisory Circular design specifications, such as elaborated on in AC 150/5325/4B, which details Runway Safety Zones (RSAs), Object Free Areas (OFAs), and Runway Protection Zones (RPZs), as it suggests in response to Comment 145 in the 2010 DEA (RDEA, Appendix K, Response 145). But these are only designed areas in runway design that are required to allow for safely aborted takeoffs or similar incidents; they in no way are intended to account for *all* potential aviation accidents in and around airports. For example, of the nine fatalities that have occurred within the ARB operational area, *none* have taken place within these designated runway areas. Thus, in responding to Comment 145 by stating that an expanded ARB, "…will continue to meet and/or exceed all FAA and State of Michigan safety standards. . .," that does not mean populated areas around the airport will be free from potential risk of incidents after takeoff, bird strikes with Canada geese, or other potential tragic incidents. It is important to remember that there have been no incidents or injuries from any of these line-of-sight incidents on the airport grounds, but that nine people have been killed over the years from aircraft crashes within two miles of ARB.

For that reason, just as, "MDOT would rather be proactive in enhancing the safety of this situation prior to a potentially catastrophic" event taking place regarding the line-of-sight issue discussed above, we recommend that the proposed 800-foot runway expansion should be denied, just as MDOT believes the 150-foot shift should be permitted. The importance of MDOT's standard of being "proactive in enhancing the safety of this situation prior to a potentially catastrophic" event holds equal weight in both circumstances, for the safety of people living near the airport as well as fliers.

VI. CONCLUSION

These comments detail why this RDEA is inadequate and fails to meet the requirements of NEPA, the NEPA regulations and FAA Order 1050.1F. For the reasons stated above, the project proposed by ARB should not be approved by either MDOT or the FAA because:

- The RDEA does not state a valid Purpose and Need, rather, ARB attempts to justify its desire for an extended runway by creating a non-existent problem (or, at least, a problem that affects a picayune portion of the aircraft operating at ARB).
- The RDEA does not establish by convincing evidence that the "critical aircraft" at ARB is a "B-II" type aircraft. In order to push its agenda, ARB has cherry-picked a few years where operations of B-II aircraft exceeded 500 operations, but it ignores the fact that in 5 out of the 8 years and 2 out of the last three years, B-II operations did not exceed 500 operations. This fact obviates the "need" for an extended runway.
- The RDEA does not address the fact that the proposed expansion brings potential risks to residents living near the airport by attracting larger and heavier jets, having aircraft take off 950 feet closer to population areas, and aircraft land just 93 feet over homes to the west of the airport.

TABER LAW GROUP PC

- The RDEA does not address the fact that the proposed expansion will have both noise and public safety impacts, violating a local Pittsfield Township noise ordinance.
- The RDEA does not address the fact that both Pittsfield and Lodi Townships have passed resolutions oppose expanding the Ann Arbor Airport runway. This puts the proposed expansion at odds with 40 C.F.R. § 1508.27(2), (4), (5) and (10).
- By carrying out the preferred alternative, ARB will be in violation of its FAA grant assurances which require it to consider the local interests of these communities, which there is no evidence presented in the RDEA that it has done.
- Further, MDOT has asserted a desire to be "proactive in enhancing the safety of ground operations by taxiing aircraft," in addressing the issue of the proposed 150-foot runway shift, emphasizing that, "MDOT would rather be proactive in enhancing the safety of this situation prior to a potential catastrophic runway incursion taking place, rather than waiting for one to take place and reacting to it afterwards." We support and agree with that logic – agreeing that the same logic should be applied to not expanding the Ann Arbor Airport primary runway as proposed because of the potential risk such an expansion could cause to citizens living around the airport in the event of an accident – employing the philosophy that, "MDOT would rather be proactive in enhancing the safety of this situation prior to a potential catastrophic" incident taking place. Proactive safety should support the 150-foot shift as the only construction that is approved for federal funding.

In keeping with the above, if this proposed expansion is not rejected based on these above arguments, we ask that the following changes to the RDEA be required before the project moves forward:

(1) Compliance with Pittsfield Township's Noise Ordinance must be considered as a required part of the project.

(2) The RDEA must address the fact that the preferred alternative is in direct opposition of Resolutions passed by both Pittsfield Township, the jurisdiction within which ARB is located, and Lodi Township, the adjacent jurisdiction. This puts the City of Ann Arbor at risk for litigation since it has signed grant agreements that state that the project must comply with local laws.

(3) The Alternative of using Willow Run Airport (YIP) to meet the RDEA's Purpose and Need must be fully considered as a "reasonable alternative" under NEPA and FAA Order 1050.1F

(4) The Alternative of adding 150 feet of runway and shifting the end of Runway 24 must be fully considered as a "reasonable alternative" under NEPA and FAA Order 1050.1F.

(5) All federal and state agency correspondence contained in Appendix D of the RDEA must be updated and that the public must be given the opportunity to comment on such updated federal and state agency correspondence prior any approval of the project.

(6) An updated noise study must be conducted that includes the effects of larger and heavier jet aircraft that an expanded runway will attract at night, and the health effects of such potential noise from positioning the runway 950 feet closer to the population center on citizens living near the airport.

(7) A Clean Air Act conformity analysis must be performed to ensure that the Project does not interfere with the State of Michigan's and the USEPA's State Implementation Plans for ozone, PM_{10} and $PM_{2.5}$.

(8) The evaluation of drinking water from wells on the airport property must be updated, and provisions for further consultation with federal and state officials required (FAA Order 1050.1E (Pages A-76-76, 17.4a).

TABER LAW GROUP PC

(9) A Wildlife Hazard Assessment that addresses the risk from Canada Geese must be drafted, approved and submitted for public comment before the project moves forward because of the risk from Canada geese surrounding the airport. This Wildlife Hazard Assessment must be approved by the FAA Administrator before the project can proceed. 14 C.F.R. § 139.337(e)(2).

Exhibit 3

2015 ANNUAL CITY OF ANN ARBOR

water QUALITY REPORT

INSIDE

FROM SOURCE TO TAP | MARCH 2016

a2gov.org/A2H2O

Water Plant 1938

Dear Valued Customer:

The City of Ann Arbor Water Treatment Services Unit is pleased to share with you our annual drinking water quality report, which is a requirement of the Safe Drinking Water Act (SDWA).

This report will tell you where your drinking water comes from, what's in it, and how to keep our water supply safe.

In the wake of the water crisis in Flint, it is understandable that our customers are concerned about their own water quality. We have a qualified staff of water utility professionals who understand the importance that the water supply plays in the overall quality of life for our community. We are dedicated to providing our customers with the best quality drinking water possible and we continue to meet or exceed all State and Federal regulatory requirements.

We work hard to provide you with safe, reliable, cost-effective drinking water and outstanding customer service

Twenty-five years ago, the City began removing the only lead components remaining in our system. These components, called "goosenecks" were used before 1950 to connect the iron water main and the galvanized iron service lines. Today there are about 100 goosenecks remaining, and the City is committed to removing them. In the meantime, these connections are covered by a protective layer of scale that prevents lead from entering the drinking water. On pages 6-7 of this report you will find a summary of the City's lead testing data and some additional facts and information about healthy plumbing.

The most recent data from Ann Arbor homes indicates that the lead level in our drinking water is well below the established action levels.

We work hard to provide you with safe, reliable, cost-effective drinking water and outstanding customer service, and we are committed to constantly improving our services and operations. Continuing to reinvest in our infrastructure is one important component of our efforts to meet your service expectations. A significant portion of the City's Water Treatment Plant dates back to 1938 and is still in service. As we begin to plan for its replacement, the City will need to adjust its drinking water rates to ensure it is in position to finance this reinvestment.

This reinvestment helps to ensure a reliable water system today and for future generations.

If you have questions about this report, or drinking water quality in the City of Ann Arbor, please contact us at (734) 794-6426 or visit us on the web at www.a2gov.org/departments/water-treatment.

Sincerely,

Brian Steglitz, PE
Manager of Water Treatment Services

Did you know...

Storm drains lead directly to the river, without treatment?

Dumping waste into storm drains, ditches, or waterways contaminates drinking water supplies, recreational areas, and wildlife habitats. Plus, it is illegal!

We need your help!

Report any dumping, spills, or construction site runoff into the stormwater system to City officials.

Sources of Drinking Water

The sources of drinking water - both tap water and bottled water - include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of the land or through the ground, it dissolves naturally-occurring minerals and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity.

Contaminants that may be present in source water include:

- **Microbial contaminants**, such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations, and wildlife.
- **Inorganic contaminants**, such as salts and metals, which can be naturally-occurring or result from urban stormwater runoff, industrial, or domestic wastewater discharges, oil and gas production, mining, or farming.
- **Pesticides and herbicides**, which may come from a variety of sources such as agriculture, urban stormwater runoff, and residential uses.
- **Organic chemical contaminants**, including synthetic and volatile organic chemicals, which are by-products of industrial processes and petroleum production, and can also come from gas stations, urban stormwater runoff, and septic systems.
- **Radioactive contaminants**, which can be naturally-occurring or be the result of oil and gas production and mining activities.

Protecting Water Quality

Source Water Assessment Program

All sources of drinking water may be susceptible to contamination. Federal regulations require states to develop and implement Source Water Assessment Programs (SWAP) to compile information about any potential sources of contamination to their source water supplies. This information allows us to better protect our drinking water sources. In 2004, the MDEQ performed a Source Water Assessment on our system. To obtain a copy of the assessment, request one by calling (734) 794-6426.

Using the information from the assessment, a susceptibility rating for each water source was determined by considering the number and location of all potential sources of contamination to our source water. The Huron River was rated “high” and the wells were rated “moderate”. These ratings do not mean that source water contamination has or will occur in our water supply; rather, they indicate a need for us to continue to carefully monitor and protect our drinking water sources.

Where does my water come from?

The City of Ann Arbor’s source water is comprised of both surface and ground water sources. About 85% of the water supply comes from the Huron River with the remaining 15% provided by multiple wells. The water from both sources is blended at the Water Treatment Plant.

Are you at risk?

Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-compromised persons such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly, and infants can be particularly at risk from infections. These people should seek advice about drinking water from their health care providers. EPA/CDC guidelines on appropriate means to lessen the risk of infection by Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline at (800) 426-4791.

Cryptosporidium

Cryptosporidium is a microbial pathogen found in surface water throughout the U.S. Although filtration removes Cryptosporidium, the most commonly-used filtration methods cannot guarantee 100 percent removal. Current test methods do not allow us to determine if the organisms are dead or if they are capable of causing disease. Ingestion of Cryptosporidium may cause cryptosporidiosis, an abdominal infection. Symptoms of infection include nausea, diarrhea, and abdominal cramps. Most healthy individuals can overcome the disease within a few weeks. However, immuno-compromised people, infants and small children, and the elderly are at greater risk of developing life-threatening illness. We encourage immuno-compromised individuals to consult their doctor regarding appropriate precautions to take to avoid infection. Cryptosporidium must be ingested to cause disease, and it may be spread through means other than drinking water. Our monitoring indicates the presence of these organisms in our source water, but not in the finished water.

TERMS USED IN THIS REPORT

- **Action Level (AL):** The concentration of a contaminant, which, if exceeded, triggers treatment, or other requirements, which a water system must follow.
- **Grains per Gallon (gpg):** A unit of water hardness defined as 1 grain (64.8 milligrams) of calcium carbonate dissolved in 1 US gallon of water (3.785 L). This is a term often used by appliance manufacturers.
- **Maximum Contaminant Level (MCL):** The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.
- **Maximum Contaminant Level Goal (MCLG):** The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety.
- **Maximum Residual Disinfectant Level (MRDL):** The highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.
- **Maximum Residual Disinfectant Level Goal (MRDLG):** The level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of the use of disinfectants to control microbial contaminants.
- **N/A:** Not Applicable
- **Not Detected (ND):** Not detected at or above the minimum reporting level - laboratory analysis indicates that the constituent is not present.
- **Nephelometric Turbidity Units (NTU):** Turbidity is a measure of the cloudiness of the water. We monitor it because it is a good indicator of the effectiveness of our filtration system.
- **pCi/L:** picocuries per liter (a measure of radioactivity).
- **Treatment Technique (TT):** A required process intended to reduce the level of a contaminant in drinking water.
- **1 part per million (ppm) or milligrams per liter (mg/L):** corresponds to one minute in two years or a single penny in $10,000. 1 ppm = 1000 ppb
- **1 part per billion (ppb) or micrograms per liter (µg/L):** corresponds to one minute in 2,000 years, or a single penny in $10,000,000.

Now It Comes With A List of Ingredients!

During the past year, we have taken thousands of water samples. This report includes information on all regulated drinking water parameters detected during calendar year 2015. Many more parameters were tested, but not detected, and are not included in this report.

REGULATED CONTAMINANTS THAT WERE DETECTED

Parameter Detected	Your Water Results		Regulatory Requirements		Likely Source
	Highest Level Detected	Results Range	EPA LIMIT MCL, TT, or MRDL	EPA GOAL MCLG or MRDLG	
Disinfection Byproducts, Disinfectant Residuals, and Disinfection Byproduct Precursors					
Bromate	6.8 ppb [1]	2.9 – 14.0 ppb	10	0	Byproduct of ozone disinfection
Chloramines [3]	2.4 ppm [1]	0.03 – 3.5 ppm	MRDL: 4	MRDLG: 4	Disinfectant added at Water Plant
Haloacetic Acids (HAA5) [3]	5.5 ppb [2]	1.7 – 11.0 ppb	60	N/A	Byproduct of disinfection
Total Organic Carbon (TOC)	54% removed [1]	47 – 64% removed	TT: 25% minimum removal	N/A	Naturally present in the environment
Total Trihalomethanes (TTHM) [3]	3.6 ppb [2]	ND – 6.4 ppb	80	N/A	Byproduct of disinfection
Radioactive Contaminants (tested in 2014)					
Radium 226 and 228	2.21 ±0.87 pCi/L	N/A	5	0	Erosion of natural deposits
Inorganic Contaminants					
Barium	10 ppb	N/A	2000	2000	Erosion of natural deposits
Chromium (total)	ND	N/A	100	100	Discharge from steel and pulp mills; erosion of natural deposits
Fluoride	0.85 ppm	0.58 – 0.85 ppm	4	4	Erosion of natural deposits; water additive which promotes strong teeth
Nitrate	0.8 ppm	0.5 – 0.8 ppm	10	10	Runoff from fertilizer use; leaching from septic tanks and sewage
Microbiological Contaminants					
Total Coliform [3]	0.7% in Oct out of 137 tested	0 – 0.7%	≤ 5% positive per month	0 positive	Naturally present in the environment
Turbidity	0.16 NTU	100% of samples ≤0.3 NTU	1 NTU and 95% of samples ≤0.3 NTU	N/A	Naturally present in the environment

[1] highest running annual average [2] highest locational running annual average [3] measured in the distribution system

Contaminants in Water

In order to ensure that tap water is safe to drink, EPA prescribes regulations which limit the amount of certain contaminants in water provided by public water systems. FDA regulations establish limits for contaminants in bottled water which must provide the same protection for public health. Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the EPA's Safe drinking Water Hotline at (800) 426-4791.

Is There Lead in My Water?

Water that comes out of the City's drinking water plant has no detectable lead, however, test results from homes in our community show there can be low levels of lead and copper in tap water, primarily caused by corrosion of household pipes, solder, and faucets.

The City adjusts the chemistry of the water leaving the plant to minimize the amount of corrosion that can occur, thus helping to reduce the risk to you!

MORE ABOUT LEAD

2014 LEAD AND COPPER RESULTS

Parameter Detected	Units	Your Water Results		Regulatory Requirements		Likely Source
		Concentration at 90th Percentile	Number of sites above Action Level	Action Level	MCLG	
Lead	ppb	2	0 out of 52	15	0	Corrosion of household plumbing
Copper	ppb	70	0 out of 52	1300	1300	Corrosion of household plumbing

2015 SPECIAL MONITORING

Parameter Detected	Units	Your Water Results		Likely Source
		Average level detected	Range	
1,4-dioxane	ppb	ND	N/A	Groundwater contamination from manufacturing process and landfills
N-Nitrosodimethylamine (NDMA)	ppb	0.0029	N/A	Byproduct of disinfection
Perchlorate	ppb	0.09	N/A	Nitrate fertilizer runoff; contamination from industrial manufacturing process
Sodium	ppm	60	48 – 67	Erosion of natural deposits; road salt and water softeners

OTHER WATER QUALITY PARAMETERS OF INTEREST

Parameter Detected	Units	Your Water Results	
		Average level detected	Range
Alkalinity, total	ppm as $CaCO_3$	51	30 – 94
Aluminum	ppm	0.022	N/A
Ammonia as N	ppm	0.13	ND – 0.30
Arsenic	ppb	ND	N/A
Calcium	ppm	32	23 – 66
Chloride	ppm	115	98 – 147
Conductivity	μmhos/cm	607	497 – 737
Hardness (calcium carbonate)	ppm	132	100 – 176
	gpg	7.7	5.8 – 10.3
Iron	ppm	ND	N/A
Lead	ppb	ND	N/A
Magnesium	ppm	24	10 – 33

Parameter Detected	Units	Your Water Results	
		Average level detected	Range
Manganese	ppb	ND	N/A
Mercury	ppb	ND	N/A
Nitrite as N	ppm	0.02	ND – 0.06
Non-Carbonate Hardness	ppm	80	44 – 123
pH	S.U.	9.3	9.0 – 9.4
Phosphorus, total	ppm	0.24	0.08 – 0.40
Potassium	ppm	3.4	N/A
Sodium	ppm	60	48 – 67
Sulfate	ppm	58	41 – 82
Temperature	°C	14.9	6.3 – 24.9
Total solids	ppm	369	321 – 447
Zinc	ppb	ND	N/A

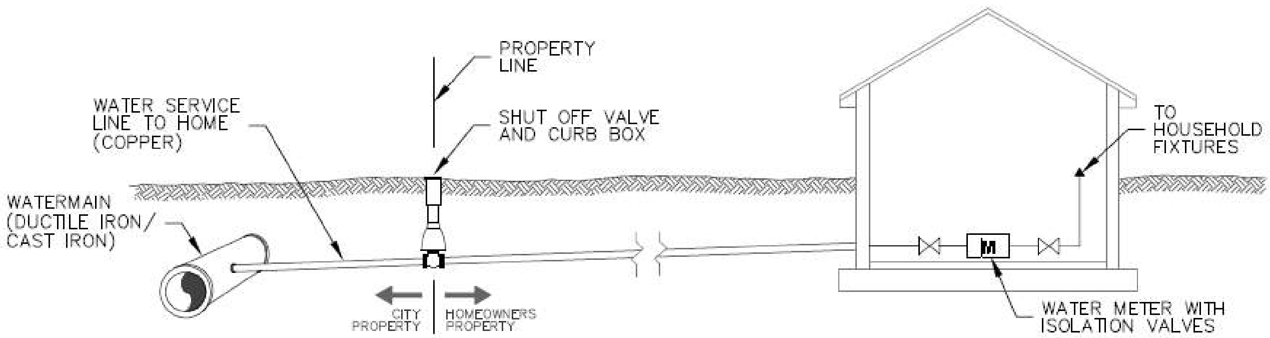
Lead Awareness in Our Community

There has been a lot of recent news coverage about lead in the Flint drinking water system. To address any local concerns, we would like to provide some information that helps to clarify how the Ann Arbor drinking water system is different.

The unfortunate situation in Flint was caused, in part, when they switched their drinking water supply source, did not use any corrosion control, and lowered the pH of the water. This caused the lead pipes and fittings in their water system to lose their protective coating and then corrode, releasing lead and iron into the water. Our water supply has been softened since 1938 and this process has optimized corrosion control. By controlling the corrosivity of the water, the amount of lead in your drinking water is kept to a minimum.

A diagram has been included below to illustrate a typical residential service line installation.

Typical Residential Service Line Installation



Healthy Household Plumbing

What you can do to minimize lead in your home:

- **Flush your pipes before drinking.** Anytime the water in a faucet has not been used for six hours or longer, flush your cold-water pipes by running the water until it becomes noticeably cold.
- **Do not cook with or drink water from the hot water tap.** Hot water can dissolve lead more quickly than cold water. If you need hot water, draw water from the cold tap and heat it on the stove or in the microwave.
- **Remove and clean your faucet screen and aerator.** Rinse out any debris then reattach them. Doing this once a month will reduce the possibility that small particles that may contain lead will build up in your faucet.
- **Consider replacing lead-containing plumbing fixtures.** A new law came into effect in 2014 limiting the amount of lead in brass faucets and plumbing.

Important information about lead

If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Ann Arbor is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting for several hours, you can minimize the potential for lead exposure by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline at (800) 426-4791 or at http://water.epa.gov/drink/info/index.cfm.

Commission OKs FY 2013 Parks Budget

Also: Windemere tennis court problems; drain project at Veterans

BY MARY MORGAN APRIL 27, 2012 at 8 am

Ann Arbor park advisory commission meeting (April 17, 2012): The action items at this month's PAC meeting focused on the upcoming fiscal year, with parks-related budget recommendations for July 1, 2012 through June 30, 2013. Sam Offen, who chairs PAC's budget and finance committee, observed that the FY 2013 budget is in better shape than in recent years.

At left is city councilmember Christopher Taylor (Ward 3), who also serves as an ex officio member of the Ann Arbor park advisory commission. To the right is Sam Offen, chair of PAC's budget and finance committee. (Photos by the writer.)

This is the second year of a two-year budget cycle, and commissioners had recommended approval of budgets for both years at their April 2011 meeting. The recent recommendations for FY 2013 include: (1) increasing the frequency of the mowing cycle from every 19 days to every 14 days; (2) increasing seasonal staffing between April 15–October 15 to maintain active recreation areas better; (3) establishing three seasonal park steward/supervisor positions to improve park maintenance and enforcement; and (4) increasing seasonal staffing at the ice arenas to improve facility cleanliness.

Fee increases at several parks and rec facilities are also part of the budget recommendations, but most have already been implemented in the current fiscal year.

The April 17 meeting included a public hearing on the renewal of the city's park maintenance and capital improvements millage, which will likely be on the November 2012 ballot. No one spoke at the hearing. In general, "there seems to be a great deal of relative silence" about the millage, parks and rec manager Colin Smith told commissioners. Few people have attended the recent public forums held by parks staff. The final forum is set for Thursday, April 26 from 6:30-7:30 p.m. at the Ann Arbor District Library's Traverwood branch, 3333 Traverwood Drive.

Parks staff gave an update on deteriorating conditions at Windemere Park's two tennis courts, and provided an initial estimate on costs to replace one or both courts at that location. No formal recommendation has been made, but options include moving the courts to another park. Commissioners discussed the need to assess the distribution and conditions of all of the city's public courts – including ones in the public school system – as well as their overall usage, to get a better idea of where the greatest needs are.

Another update came from an engineer at the Washtenaw County water resources commissioner's office, who described a drain replacement project that will affect Veterans Memorial Park later this year. Also related to Veterans Memorial, the request for proposals (RFP) for a skatepark there has been issued. [.pdf of skatepark RFP] The goal is to solicit proposals for a consultant to handle design and oversee construction of the skatepark, which will be located on city-owned property.

During public commentary, commissioners were given an update on the nonprofit Project Grow, which has several gardens located in city parks and is celebrating its 40th anniversary this year. Another speaker urged commissioners to take control of the parking lots in city parks, and possibly increase revenues by installing metered parking.

Parks & Rec Budget Recommendation

Park commissioners considered two resolutions related to the city's fiscal year 2013 budget, for the year beginning July 1, 2012 through June 30, 2013. It's the second year of a two-year budget planning cycle. PAC had previously recommended approval of budgets for both years at its April 2011 meeting. The parks budget is part of the city's overall budget, which city administrator Steve Powers proposed at the April 16 meeting of the Ann Arbor city council.

Most of these changes have already been implemented, as part of the current year's budget. Colin Smith, the city's parks and rec manager, reminded commissioners that there will be no increase in budgeted expenses. These changes will be made within the budget plan that was discussed last year for FY 2013, when the FY 2012 budget was formally adopted. [.pdf of budget resolution adopted by council for FY 2012, including parks-related items]

The portion of the city budget relating to parks is separated into two parts: (1) park operations; and (2) parks and recreation.

Sam Offen, who chairs PAC's budget and finance committee, noted that the budget is in better shape than in recent years. He joked that it makes his job much easier.

Parks & Rec Budget Recommendation: Parks Operations Budget

PAC was asked to approve recommendations for the FY 2013 parks operations budget, which includes the following proposed changes: (1) increasing the frequency of the mowing cycle from every 19 days to every 14 days; (2) increasing seasonal staffing between April 15–October 15 to maintain active recreation areas better; (3) establishing three seasonal park steward/supervisor positions to improve park maintenance and enforcement; and (4) increasing seasonal staffing at the ice arenas to improve facility cleanliness. [.pdf of parks operations budget recommendation]

There was considerable discussion about whether to change the wording on the recommendation for the mowing cycle. Tim Doyle initially felt it sounded too much like a dictate rather than an objective, and preferred deferring to staff's judgement on the exact number of days in the cycle. After some wordsmithing on a possible amendment, Christopher Taylor – PAC's ex officio member who also serves on city council – was asked whether his council colleagues would understand the intent. "Contextually, it's plain enough," he said.

Ultimately, PAC reached a consensus not to change wording on the recommendation.

Outcome: Commissioners voted unanimously to recommend approval of the FY 2013 parks operations budget.

Parks & Rec Budget Recommendation: Parks & Rec Budget

In a separate resolution, PAC was asked to recommend approval of the FY 2013 parks and recreation budget. The resolution commended parks staff for its work, and made several general recommendations: (1) reduce energy expenses to reflect the benefit of infrastructure energy improvements at recreational facilities, including Cobblestone Farm and Mack Pool; (2) reduce materials and supplies used to maintain various facilities as a result of recent improvements; (3) reduce water usage expense to reflect actual usage better; (4) eliminate unnecessary software installations where appropriate; (5) increase revenue by initiating additional programming at the Argo Cascades; and (6) increase revenue by increasing fees for admission to swimming pools. [.pdf of parks & rec budget recommendation] [.pdf of fee increases]

Most of these items have been started in the current fiscal year, Offen noted, and will continue into FY 2013.

Outcome: Commissioners unanimously recommended approval of the FY 2013 parks and recreation budget.

Parks Millage Renewal: Public Hearing

No one spoke during a public hearing on the renewal of the city's park maintenance and capital improvements millage, which will likely be on the November ballot.

Park commissioners had been briefed by staff about the millage renewal at PAC's March 20, 2012 meeting.

John Lawter, PAC's vice chair who was presiding over the meeting in the absence of chair Julie Grand, noted that two of the four public informational forums regarding the millage had been held.

[The third forum took place on Monday, April 23. The final one is set for Thursday, April 26 from 6:30-7:30 p.m. at the Ann Arbor District Library's Traverwood branch, 3333 Traverwood Drive.]

Colin Smith, parks and rec manager, noted that Grand had wanted to schedule some of the public forums prior to the public hearing at PAC, and prior to a vote by PAC on whether to recommend millage renewal. That way, PAC could respond if any issues arose. However, Smith added, "there seems to be a great deal of relative silence," and nothing has come up to indicate that the city is on the wrong track in seeking renewal. [At an April 11 forum held at Cobblestone Farm, several city parks staff, PAC commissioners, city councilmember Jane Lumm, and two members of the media – from The Chronicle and WEMU – showed up. But only one member of the public came: Eric Meves, a board member at Project Grow who also spoke during public commentary at the April 17 PAC meeting (see below).]

From left: Greg McDonald, assistant manager of city operations for Community Television Network (CTN), explains a camera problem to Colin Smith, the city's parks and recreation manager. The controller that allows CTN staff technicians to remotely control cameras in city council chambers wasn't working during the April 17 park advisory commission meeting. CTN staff instead adjusted the cameras manually prior to the meeting, to capture wide angle views of the proceedings.

Gwen Nystuen observed that it's hard to get people excited now about a vote that won't happen until November. She said she hadn't heard anything unfavorable about the millage, and that people in Ann Arbor are very supportive of parks. "I'm optimistic," she said.

Sam Offen asked whether there were any significant comments or feedback from the first two forums. Lawter reported that the one person at the forum he attended was supportive. [That person was Meves.] Nystuen praised the staff – she said they had done a good job of answering questions at the first forum about how the budget was prepared.

Informational handouts are being distributed, and Smith pointed out that information about the millage renewal is also available on the city's website.

Windemere Park Tennis Courts

Parks planner Amy Kuras gave a presentation on the tennis courts at Windemere Park, a nearly four-acre parcel on the city's northeast side, north of Glazier Way between Green and Earhart roads. There was no action requested of PAC at this meeting – the staff just wanted to update commissioners on the situation.

The courts were initially built in 1986, then color coated in 2007. Repairs to cracks in the court were attempted in 2009, Kuras said, but failed because of poor soil conditions. The city also attempted to install new net posts in 2009, but that also failed.

In 2010, the city took soil borings in five parts of the park. The borings revealed saturated organic soil and fill, particularly in areas located near the tennis courts in the west part of the park.

Part of the problem is a high water table, Kuras said. In fact, the parks staff have noted higher water tables throughout the city, she added. The only hard data that the city has collected on the water table is at the municipal airport, and there the water table measures between 2-7 feet below the surface now, compared to 15 feet below the surface 50 years ago. Jen Lawson, the city's water quality manager, attributed the change to a variety of factors, Kuras reported, including climate change and more impervious surfaces in the city.

Kuras presented a chart showing cost estimates to replace either one or both courts at the current location. She based her estimates on work done for tennis courts at Veterans Memorial Park and West Park. The total would be $181,377 for two courts at Windemere, or $107,408 for one court. [Link to chart of itemized replacement costs.]

The options to consider, Kuras said, include: (1) replacing both tennis courts at the current location, (2) replacing the courts in another part of Windemere Park, (3) replacing only one court, (4) removing

the courts, or (5) possibly putting the courts in another park.

Matt Warba, the city's acting field operations manager, told commissioners that he's frustrated by the situation. The staff has attempted several repairs, but with water at just two feet below the surface, it's difficult. There's a likelihood that having tennis courts at that location isn't reasonable, he said. But he understands the value to the neighborhood, and the staff is still working on getting some firm numbers and options to consider. There's no easy or quick solution, he said, but they're working on it.

Cracked pavement at the Windemere Park tennis court. (Image provided by city staff in a slide presentation to PAC.)

Windemere Park Tennis Courts: Public Commentary

Jeff Alson told commissioners that he has lived near the park since the late 1970s. He bought his home there in part because of the park. There are a lot of tennis players in the neighborhood, and there are a lot of young children in the area so demand could grow. But because of water issues there's only one court that can be used. Last summer, he hardly played there at all. Alson said he understood that there are problems with water that make maintenance of the courts more expensive. But he emphasized that the courts have held up well for at least the last 10 years, and he would consider it a good investment. It would be disappointing to him if the courts were removed. Alson concluded by thanking commissioners for their service to the city.

Windemere Park Tennis Courts: Commission Discussion

David Barrett asked whether the water table is the same throughout the park. Yes, Kuras said, but the soil composition is different at certain locations in the park – that's a factor, too. She clarified that there are water table issues at other parks, but nothing to the degree they're seeing at Windemere.

Barrett recalled that when the city decided to put in rain gardens at Burns Park, they were slow to let the community know about it. He wondered what kind of outreach was happening for the tennis courts at Windemere. Colin Smith, parks and recreation manager, indicated that outreach would occur when the staff had more information to share. If it makes sense to move the tennis courts, the neighborhood would need to be engaged, he said.

Tim Doyle asked is there's evidence of this same kind of problem at other city tennis courts. He said he's encountered it on a similar project he's working on near Honey Creek, on the west side of town. Warba said that certainly there are areas in the parks that are wetter than they've been in the past. But the Windemere courts are the worst by far.

Sam Offen noted that there are a lot of city tennis courts on the west side of town, but he wondered how many there were on the northeast side. Kuras reported that there are three courts in Leslie Park and two in Sugarbush Park, and it might be possible to accommodate new tennis courts somewhere in Foxfire North Park. All of those parks are in northeast Ann Arbor.

Jeff Alston, a resident who'd spoken during public commentary, pointed out that the courts at Sugarbush are too short for adults to play – they hit the back fence with their rackets, he said.

Gwen Nystuen said she didn't know too much about tennis courts, but that it seemed like the city should assess the distribution and conditions of all of its courts, as well as their overall usage, to get a better idea of where the greatest needs are.

Commissioners and staff also discussed the availability of tennis courts at Ann Arbor public schools, noting that certain times of day and certain days of the week those courts are heavily used by students. Tim Berla noted that Ann Arbor Rec & Ed runs tennis leagues, as does the Ann Arbor Area Community Tennis Association. He pointed out that court conditions aren't just a concern for the city parks – a sinkhole developed at the relatively new tennis courts at Skyline High School, putting one of

the courts out of commission. Berla suggested looking at other materials, such as clay, which he said required more maintenance but wouldn't crack.

Assuming there's need for more tennis courts on the northeast side of town, Berla wondered whether the former Pfizer property – now owned by the University of Michigan – could be a possible location for new courts. He noted that there's a lot of unused land there, as well as available parking.

Drain Project at Veterans Memorial Park

Scott Miller, an engineer with the Washtenaw County water resources commissioner's office, was on hand to give a presentation about a drain project that would affect Veterans Memorial Park. He said the county had been petitioned by the city to do this project. It's referred to as the West Park Fairgrounds project, which is the name of the drain that runs through that section of town – on the west side of town, in the former fairgrounds area. Miller acknowledged that it was a bit confusing, given that a park in a different location is called West Park.

Scott Miller of the Washtenaw County water resources commissioner's office describes an upcoming drain project that will affect Veterans Memorial Park.

The upper end of the drain is located in the Maple Village Shopping Center, where Kmart and Plum Market are located. The drain starts out as a 30-inch pipe and quickly transitions to a 54-inch pipe and then a 66-inch corregated metal pipe as it runs toward town. The pipe runs through Veterans Memorial Park, crosses under Dexter Road and heads east, eventually connecting to a pipe that contains another branch of the Allen Creek.

The city conducted video inspection of the pipe and found several sections that are cracked and corroded, resulting in leaks. Portions of the pipe were clogged with debris. [The city council voted at its Sept. 20, 2010 meeting to petition the county water resources commissioner for this project, estimated to cost roughly $2 million. It will be repaid by the city in annual installments over 15 years.]

Miller said the county staff began work last fall, first clearing the debris and then conducting another video assessment. That revealed two sections of the pipe that have a significant sag, and result in water being held in those sections year-round. One sagging section is in the parking area in the shopping center. Another is in the north side of the park's parking lot that's accessed off of Dexter Road. The preliminary design is to dig up the two sections of sagging pipe and replace them. For the rest of the pipe, the plan calls for putting in a cast lining to reinforce the pipe structurally.

The project would cause minimal disruption, he said, but would include some impact to the parking lot and a small portion of the area west of one of the ballfields. The county is coordinating with the city, which is doing road work and water main replacement along Dexter Road, as well as upcoming work to renovate the ballfields in the park.

The project is in the design phase now, Miller said, with construction expected to begin in the fall.

Drain Project at Veterans Memorial Park: Commission Discussion

Gwen Nystuen asked for more details about how much land would be dug up for the project. Miller reported that in the Maple Village lot, a section about 15 feet wide and 150 feet long would be excavated. In Veterans Memorial Park, the work would be about 15 feet wide and 190 feet long.

Nystuen also commented on the confusing name of the project, and Miller agreed: "It's raised confusion at a lot of levels," he said, but they don't have much latitude to change it.

David Barrett pointed out that there's already disruption to the park – a big pile of dirt has been dumped by the ballfield. He wondered if the county had also coordinated with Ann Arbor Rec & Ed, which runs softball leagues in the park. Miller said the drain work hasn't yet started, so the excavated dirt isn't from their project. Matt Warba, the city's acting field operations manager, clarified that it was likely related to road construction there. Parks and rec manager Colin Smith said the parks staff has been coordinating with Rec & Ed since last year regarding work in the park.

Sam Offen asked about the project's timeframe. It will likely take about two months, Miller replied, but more if there's a lot of rain. In response to another query from Offen, Miller said the county is mindful of the potential flooding impact downstream, but noted that this project isn't intended to increase capacity dramatically. There will be more efficient flow, however.

Ann Arbor park advisory commissioner David Barrett.

Tim Berla clarified that Rec & Ed has cancelled its fall season, which starts in August, because of renovation work on the ballfields at three parks, including Veterans. [PAC had recommended those renovations at their February 2012 meeting.] He asked whether it would be possible to do the park portion of the drain project first, to ensure it would be finished by the spring season. Miller said it probably wouldn't matter – the entire project is expected to be done by the spring of 2013 – but he would look into it.

Berla also asked whether the proposed skatepark – to be located in another part of Veterans Memorial Park – would affect the drain project, in terms of adding runoff. Miller said that although the addition of any impervious surfaces would affect runoff, the pipe is underutilized and has the capacity to handle it.

Smith noted that one of the elements of the skatepark design, as reflected in the request for proposals, will be to include stormwater management that meets or exceeds city standards.

Communications & Commentary

Every meeting includes opportunities for public commentary and communications from commissioners and staff.

Comm/Comm: Public Commentary – Parking in Parks

During public commentary, **George Gaston** told commissioners that he recently visited the University of Michigan's Matthaei Botanical Gardens – it's a lovely place, he said. He had noticed that UM now has metered parking there at $1.20 per hour, between 8 a.m. and 8 p.m. Gaston noted that the city leases its Fuller Park parking lot to UM. It was supposed to be a temporary arrangement, but it's been going on for about 20 years. He wondered if the city has considered taking back control of that lot and and making it a metered lot, too. UM hospital employees use it 24/7, Gaston said, but only pay for part of that time. It could be a great revenue source for the city.

Gaston noted that people park their vehicles all day at Island Park and West Park, as two examples. And with UM planning to build a parking structure on Wall Street that would add another 500 spaces to that area, it might be possible to forego leasing the 18 spaces at Riverside Park to UM and adding metered spaces instead. "You might gain real money out of this," Gaston said. There's precedent in the city for 24-hour metered lots – at the Amtrak station on Depot Street, for example. Right now, it seems the city is undercharging the university for parking. With meters, the lots would be available to anyone if they paid. It might make sense to look into this, he concluded.

Comm/Comm: Project Grow – Public Commentary

Eric Meves, a board member of Project Grow, gave commissioners an overview of the nonprofit. He started by referring to Gaston's comments about parking, noting that Project Grow had to buy parking tags at Matthaei for its gardeners there this year. Meves told commissioners that Project Grow is celebrating its 40th anniversary this year, and he's gardened with the group for 39 of those years.

Several Project Grow gardens are in city parks, so he wanted PAC to become familiar with the organization. It's an educational organization, with assistance for low-income residents. Although the nonprofit has received city funding in the past, it no longer receives public money, he noted.

Project Grow doesn't own any land. About a third of the gardens are located in Washtenaw County parks, and a third on Ann Arbor public school property. The remaining third is evenly divided between

UM land, private property, and city of Ann Arbor parks. About 300-350 families have garden plots each year, Meves said. People do it to grow food, but also for outdoor exercise and to be in a pleasant environment, he said. There's also an element of community – being with your fellow gardeners.

Eric Meves, treasurer of the Project Grow board.

The nonprofit grosses about $40,000 to $50,000 annually, Meves said. About 60% of that comes from plot fees – it costs about $130 for a full plot. About 20% of revenues come from fundraising, primarily through an annual plant sale. The remaining 20% comes from an organic gardening class that Project Grow developed for Washtenaw Community College.

Roughly half of those revenues allow Project Grow to have one half-time employee who works out of his house, Meves said. The group relies on volunteers and a working board. The rest of the funds are used to pay for things like water, utilities, insurance and capital improvements. There are about 40 people on a waiting list for gardens now – demand for gardens is about two to three times what Project Grow can provide, he said.

Meves unfurled a map that he said was made with the help of Merle Johnson and Dan Rainey of the city's information technology department. It showed possible additional locations for gardens within the parks system.

Comm/Comm: Project Grow – Manager's Report

Later in the meeting, Colin Smith reported that parks planner Amy Kuras has been working with the Project Grow managing director [Kirk Jones] to draft an agreement that will outline the formal relationship between the city and the nonprofit. It's been a few years since the city funded Project Grow, he said, but because the group uses city parkland, there's still a relationship. The agreement will stipulate what the procedures are for putting gardens into parks. There have been varied reactions to having gardens in the parks, depending on the neighborhood, he noted. Parks staff will share the agreement with PAC when it's ready, he said.

Tim Berla asked if there's anything PAC or the city can do to help Project Grow identify potential locations for more gardens. Kuras said she works with the organization – sometimes she'll be contacted by someone in a neighborhood who's interested, and she'll in turn contact Project Grow, or sometimes Project Grow comes to her. There are certain requirements, she noted. The land needs to be in a sunny area, and have access to a water source. The city also needs to hold a public meeting if a park is being considered for gardens, and sometimes neighbors don't want it, she said.

From left: Park advisory commissioners Tim Berla and John Lawter. Lawter, who chaired the April 17 meeting in the absence of chair Julie Grand, was reviewing procedural rules with Berla before the meeting. Berla's advice: "No one ever did time" for flubbing Robert's Rules.

Smith noted that the agreement with Project Grow will include details about how PAC can be involved in the process of selecting new locations.

Gwen Nystuen said she appreciated that Eric Meves had spoken to PAC during public commentary. She hadn't realized how many people are involved, and how the city provides relatively little land for

the group. It's useful information, she said, especially given the growing interest in the local food movement.

Tim Doyle clarified with Smith that there is no relationship between Project Grow and the city's greenbelt program.

Comm/Comm: Skatepark RFP

Smith reported that the request for proposals (RFP) for a skatepark at Veterans Memorial Park would be issued the following day. [.pdf of skatepark RFP] The goal is to solicit proposals for a consultant to handle design and oversee construction of the skatepark, which will be located on city-owned property.

Tim Doyle asked how the project would be funded. Smith replied that there are three sources for the roughly $1 million cost of the project: (1) private donations – primarily solicited through the Friends of the Ann Arbor Skatepark; (2) a $300,000 state grant; and (3) up to $400,000 in matching funds from the Washtenaw County parks and recreation commission. The Ann Arbor Area Community Foundation is acting as fiduciary for the project.

The city's contribution will be the land and staff time to manage the process, Smith said, not money. It will be a city-owned asset, he said.

In terms of process, a selection committee – which will include members of the Friends of the Ann Arbor Skatepark, as well as city and county representatives – will be relied on to make a recommendation for the designer. That recommendation will be reviewed by PAC. PAC commissioner David Barrett will serve on the committee. Park planner Amy Kuras is the city's point person on the project.

Construction is expected to start in the spring of 2013.

Gwen Nystuen asked about the relocation of pathways that will be required because of the skatepark location. Kuras noted that some pathways in Veterans Memorial Park are being redone as part of the Dexter Avenue improvement project that's currently underway. Paths that connect to the skatepark will be designed as part of the overall skatepark design, she said.

Comm/Comm: Manager's Report – Market Manager

Smith reported that the field had been narrowed to two candidates to replace Molly Notarianni, who left the job of public market manager earlier this year. He said he hoped to have finalized a hire by PAC's May 15 meeting.

Comm/Comm: Manager's Report – Argo Cascades

The same day as the PAC meeting, the consultant who designed the new canoe/kayak bypass by Argo Dam – Gary Lacy of Boulder, Colo. – was testing the series of drop pools along with city staff. Smith said he had hoped that Lacy would have the time to give an update to PAC about the new Argo Cascades, but the morning had been chilly and Lacy had gotten a late start on the testing, so he wasn't able to attend the meeting.

A grand opening of the Argo Cascades is planned for June, but it will be open to the public before that. May 5 is the date for the first trips from the Argo Pond livery to Gallup Park, Smith said.

Present: David Barrett, Tim Berla, Doug Chapman, Tim Doyle, John Lawter, Karen Levin, Gwen Nystuen, Sam Offen, councilmember Christopher Taylor (ex-officio). Also Colin Smith, city parks and recreation manager.

Absent: Julie Grand, councilmember Mike Anglin (ex-officio).

Next meeting: PAC's meeting on Tuesday, May 15, 2012 begins at 4 p.m. in the city hall second-floor council chambers, 301 E. Huron St., Ann Arbor. [confirm date]

   We encourage action, soon. This problem has existed for a long time without solution. Just listen to the nearby neighborhoods say the demand is there and fix a community resource. Seems like a sunk cost without adequate maintenance.

   Consider a local bond issue or ~ and do something.

TABLE OF CONTENTS

I. STATEMENT OF FACTS

A. The Airport.

Ann Arbor Municipal Airport (ARB) is a general aviation airport located entirely within the boundaries of Pittsfield Charter Township, Michigan ("Pittsfield"). According to AirNav.com, ARB has two runways, a concrete runway 3,505 feet long and 75 feet wide, and a turf runway 2,750 feet long and 110 feet wide. Exhibit 1. AirNav also notes that ARB is the base for 166 aircraft, consisting of 137 single engine airplanes, 16 multi-engine airplanes, 1 jet airplane, 11 helicopters and 1 ultralight. *Id*. ARB averages 161 operations per day, 64% of those operations are local general aviation, and 36% are transient general aviation operations.[1] *Id.* Although located outside the city limits of Ann Arbor, the City of Ann Arbor (the "City") owns and operates the airport.[2] Despite the fact that ARB is located entirely within the boundaries of Pittsfield, the township has no voting representation on any committee, council or board tasked with the management or the operation of ARB.[3]

B. The Petitioners.

1. Pittsfield Charter Township.

Pittsfield is a "charter township." Under Michigan law, a "charter township" is a municipal corporation that has been granted a charter, allowing it certain rights and responsibilities of home rule that are generally intermediary in scope between those of a city and a village. A charter township has greater protections against annexation of a township's land by

---

[1] These figures are for the 12-month period ending December, 2011.

[2] Official FAA records actually list "Roger W. Fraser" as the owner of ARB without noting that Roger W. Fraser was the City Administrator for the City until 2011. Exhibit 2. The fact that the Airport is actually owned by the City, however, is noted on ARB's website: http://www.a2gov.org/government/publicservices/fleetandfacility/Airport/Pages/default.aspx.

[3] Both Pittsfield and Lodi Township have a non-voting *ex officio* member on the "Ann Arbor Municipal Airport Advisory Committee." *See* Exhibit 3. However, "the purpose of the [Ann Arbor Municipal Airport Advisory Committee] is to make recommendations to the Ann Arbor City Council regarding the construction and operation of the Airport." *Id.*

cities and villages. As a charter township, Pittsfield has established a variety of municipal services, such as a police force, fire department, assessors and is governed by a comprehensive zoning ordinance. Since ARB is within Pittsfield's corporate jurisdiction, the township provides services to ARB, as well as being subject to the township's ordinances limited only by the agreements between Pittsfield and the City.

The City, in the past, expressed an interest in annexing the property on which ARB sits. This resulted in the 1978 agreement between the City and Pittsfield Township regarding the airport. Exhibit 4. This agreement was modified in 2010. Exhibit 5.

2. Committee for Preserving Community Quality, Inc.

The Committee for Preserving Community Quality, Inc. (CPCQ) is a not-for-profit corporation consisting of approximately 400 residents of the Pittsfield and Lodi Townships and the cities of Ann Arbor and Saline. CPCQ was incorporated in April, 2010, as a community action group for residents of the communities surrounding ARB who feel the airport expansion is "both dangerous and unjustified."

C. The Proposed Project.

According to the draft Environmental Assessment[4] ARB has several issues that impact aviation safety. First, there is a "line of sight" issue whereby aircraft waiting to take off in the holding area for Runway 24 may pass out of sight of the control tower. In addition, because the northeast end of Runway 24 is a few hundred feet from State Road, a busy Township road, aircraft have to approach at slope of 20:1 instead of a more optimal 34:1. Moreover, according to the draft EA, State Road will only get bigger and wider, thereby exacerbating the problem.[5] Thus, according to ARB and MDOT, one goal of the proposed project is to move Runway 24

---

4 The City of Ann Arbor issued a draft Environmental Assessment in March, 2010. Exhibit 26.

5 The FAA, in its comments to MDOT, noted that the draft EA does not seem to substantiate the need for "a clear 34:1 approach surface to the east end of the runway." Exhibit 18, pp.4-5.

150 feet to southwest, resolving both the line-of-sight issue and the slope issue. The current 150 feet of runway at the northeast end of Runway 24 would remain as a displaced threshold.

If the project had ended there, Pittsfield and CPCQ (collectively, "Petitioners") may not have objected to it since it has a vested interest in the safe operation of the airport. However, the City also wanted to tack on an additional 800 feet at the southwest end of Runway 24 to make the runway 4,300 feet long. This runway extension, ARB and MDOT have argued, is necessary to "[e]nhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions." Thus, all told 950 feet of runway would be added to the southwest end of Runway 24 and 150 feet of the current runway would remain as a displaced threshold. However, there is no aviation safety issue connected to the extension of the runway.[6]

This extension of the Runway 24 qualifies as a "major runway extension" as that term has been defined by the FAA and the courts. The runway extension will permit the accommodation of aircraft that would result in an increase in noise of three decibels. *See Suburban O'Hare Commission,* 787 F.2d at 199-200; and *Town of Stratford v. FAA,* 285 F.3d 84, (D.C. Cir. 2002).

D. Petitioners' Opposition to the Proposed Project.

Petitioners' opposition to the proposed project dates back to the first time Ann Arbor proposed to extend the runway to allow bigger and noisier aircraft into ARB. On January 22, 2007, the Ann Arbor City Council unanimously approved Resolution R-31-1-07, formally adopting the airport's previous Airport Layout Plan (ALP) and called for "staff to bring back a

[6] The draft EA attempts to attach a safety concern to the extension, mentioning that aircraft had a tendency to overrun the runway at ARB. Ultimately, though, each of the runway overruns was found to be unrelated to the length of the runway and due to pilot error, a fact that ARB and MDOT admit in their response to FAA's comments. Exhibit 19, pp.14-15.

separate proposal regarding extending the runway within the next 60 days and that notification of the proposal be sent out to citizens in the surrounding area." Exhibit 6; *see also* Exhibit 31. Unfortunately, not only did the City's staff not return to a public council meeting within 60 days with an expanded runway plan, the City's staff also failed to inform "citizens in the surrounding community" of its actions for twenty months. Instead, on February 28, 2007, just 37 days after its initial City Council Resolution order, the City Staff, citing that Resolution as a basis, submitted a proposal for an 800-foot extension of primary Runway 6/24 at ARB to the Michigan Department of Transportation – Aeronautics Division (MDOT). Exhibit 7. No corresponding notice was given to Pittsfield or to the "citizens in the surrounding area."

On September 12, 2007, the proposed ALP was amended at the request of MDOT to allow for the 150-foot southwesterly movement of the entire primary runway,[7] to provide for the widening of State Street-State Road, which MDOT conceded could not be funded for decades.[8] Neither Pittsfield nor the "citizens in the surrounding community" had yet been informed by the applicant or MDOT about the proposed ALP, which calls for an extension of Runway 6/24 on land within Pittsfield's jurisdiction. The ALP finally was approved by MDOT on April 23, 2008, and presented to the Federal Aviation Administration for approval on June 4, 2008.

In a June 23, 2008, letter from David L. Baker, Manager, AIP Programs of MDOT's Airports Division of the Bureau of Aeronautics and Freight Services, MDOT indicated to the City that the FAA concurred with the approval of the ALP. Yet neither MDOT nor FAA informed Pittsfield or the citizens of the surrounding communities of either MDOT's or the FAA's approval of the ALP. In fact, it was not until August 22, 2008, that the City first

---

7 In the end, then, the Project consisted of adding 950 feet of runway to the southwestern end of existing Runway 6/24: 150 feet to move the runway away from State Road and 800 for extending the runway to 4,300 feet. The existing 150 feet of runway at the northeastern end of the runway would remain as a displaced threshold.

8 At this point in time, it is unclear whether the road will be widened at all or, if so, to the west or to the east.

officially provided Pittsfield with the plans and notification of the proposed ARB expansion and detailed proposed changes in the ALP. These documents were required to be provided to Pittsfield more than 18 months earlier under both the January, 2007, Ann Arbor City Council Resolution and under a separate 1979 Policy Statement.[9] *See* Exhibit 6 and 4, respectively. This is also contrary to the grant assurances that the City agreed to, which indicate that prior to receiving any federal funds for the Airport Layout Plan, it must give "fair consideration to the interest of communities in or near where the project may be located" (Grant Assurance 7). *See also* Grant Assurance 6. It is noteworthy, that this first notification from Ann Arbor to Pittsfield is dated 59 days after the FAA approved the revised Ann Arbor Airport ALP. Under 49 U.S.C. § 46110, routine appeals of final agency "orders" are barred after 60 days. Thus, Pittsfield was effectively barred from legally objecting to the Ann Arbor ALP before even being notified by Ann Arbor about its revised ALP.

Unable to file a legal action to stop the City from moving forward with its illegal ALP, Pittsfield responded to Ann Arbor's August notice, objecting to the proposed expansion, citing the (1) increased noise that would be generated, (2) larger aircraft that would be attracted, and (3) and greater use by heavier aircraft that could result.[10] Despite Pittsfield's opposition to the proposed expansion of ARB, the Ann Arbor City Council approved the revised Ann Arbor ALP on September 22, 2008, without considering Pittsfield's objections, or those of Lodi Township, another township close to ARB.

[9] The 1979 policy states, *inter alia*, that "[p]lans for municipal construction on Airport lands must be submitted to the Township for review and comment." Exhibit 4, p.3. The 1979 Policy was amended after the modification of the ALP. Exhibit 5. The amendment makes clear what Pittsfield already thought was plainly obvious under the 1979 policy - that the City must notify Pittsfield prior to modifying the ALP. *See* Exhibit 5, p.2, ¶ 4.

[10] It should also be noted that the new ALP raises the weight limit of aircraft at ARB to 45,000 (single axle) and 70,000 (double axle). Exhibit 31. This change was never discussed by the Ann Arbor City Council, who still believes that the weight limit at ARB is 20,000 pounds.

On March 24, 2009, Pittsfield unanimously approved a Resolution Opposing Proposed Expansion of the Ann Arbor Municipal Airport Runway. Exhibit 8. That Resolution cites several reasons why the runway at ARB should not be expanded. Primary among those reasons is the fact that ARB is "immediately adjacent to a residential area" and that the existing "width and length" of the runway "has not posed any substantial safety concerns in the past." *Id.* In addition, the Resolution states that:

- The proposed changes would shift the runway dangerously close to a busy township road (Lohr Road) and closer to dense residential subdivisions;

- The runway expansion will significantly increase air traffic volumes and noise pollution experienced by residential subdivisions in the vicinity of ARB, thereby resulting in a decline of residential home property values and impacting Pittsfield's tax base;

- The City has not fully demonstrated the economic and safety justifications for undertaking the proposed runway expansion;

- The City has not taken into consideration the negative safety implications such a runway expansion may impose on surrounding residential subdivisions by expanding a runway closer to residential subdivisions.

Id. Lodi Township, which is adjacent to Pittsfield on the west side and also impacted by ARB, passed a similar resolution on May 12, 2009. Exhibit 9. Ann Arbor, MDOT and the FAA did not respond to either Pittsfield or Lodi Township's resolution, despite repeated requests to consider the communities' input into the proposed revision of the ALP and the proposed expansion of ARB.

On June 17, 2009, the FAA issued a Notice of Intent to Prepare an Environmental Assessment and Conduct Citizen Advisory Meetings. Exhibit 10. Although the Notice of Intent stated that "[d]uring development of the draft EA, *a series of meetings* to provide for public input will be held to identify potentially significant issues or impacts related to the proposed action that should be analyzed in the EA" (*id.* (emphasis added)) the only real opportunity for any public discussion -- with elected public officials present -- about the proposed expansion plan was before the Ann Arbor City Council, where speakers must call-in to register in advance. Only the first ten callers on the day of Council meetings are permitted to speak. Speakers are limited to three minutes. Such a process typically has a stifling effect on open and candid discussions for subjects as complex as an airport ALP and runway expansion proposal.

Prior to the FAA's issuance of the Notice of Intent, in the Spring of 2009, a "Citizens Advisory Committee" (CAC) was appointed to advise the preparers of the Environmental Assessment. The CAC was initially comprised of:

- The Ann Arbor Airport manager;
- The chairman of Ann Arbor's Airport Advisory Committee;
- An Ann Arbor 4th Ward resident, who is also a member of the Airport Advisory Committee;
- An Ann Arbor 3rd Ward resident, who is also a flight instructor at the airport;
- Another pilot based at the airport, who is also chief pilot of Avfuel, which stands to be the single greatest beneficiary from the runway extension;
- Another airport flight instructor, who is also a member of the airport-based FAA Safety Team;
- A citizen member from Ann Arbor's 5th Ward;
- A representative from Ann Arbor's 2nd Ward, who is also a member of the Ann Arbor City Council;
- A representative of the Washtenaw Audubon Society, which conducted a previous study that found no Canada geese among 38 other species on the airport;
- Lodi Township Supervisor Jan Godek; and,
- Pittsfield Township Deputy Supervisor Barbara Fuller.

Only after extensive political pressure was applied were two additional outside members added to the CAC:

- Shlomo Castell, a commercial passenger airline pilot from the Stonebridge Community Association in Pittsfield Township, and

- Kristin Judge, Washtenaw County Commissioner from District 7, which includes Pittsfield.

For an airport located in Pittsfield Township that most dramatically impacts Pittsfield and Lodi Townships and Ward 4 of Ann Arbor, the CAC was dominated by the City and airport members who stood to benefit from the expansion. It was apparent that ARB intended the CAC to under-represent those immediately outside the airport perimeter whose safety could be placed at greater risk by any expansion. Ultimately, however, the CAC was a powerless committee intended only to provide the façade of public participation in an essentially authoritarian decision-making process. The CAC only met three times, with no opportunity for public participation. According to records available to Petitioners, CAC first met on May 4, 2009, to receive information about the proposed project. Exhibit 11. The second meeting was held on July 20, 2009, at which some of the initial findings were presented by ARB's consultants. Exhibit 12. No members of the public were allowed to attend or ask questions. *Id*. Instead, members of the CAC were expected to interact with their "constituencies" and express to the committee their comments and concerns outside of the CAC. *Id.* The final meeting was held on February 22, 2010, when the executive summary of the draft EA was presented to the CAC. Exhibit 13.

This was not the "series of meetings to provide for public input … held to identify potentially significant issues or impacts related to the proposed action that should be analyzed in the EA" that MDOT and the FAA promised. The public was not invited to participate at the CAC meetings. Instead, the members of the CAC received information from ARB's consultants and were expected to relay it back to their "constituencies." When the CAC had suggestions or recommendations, they were often ignored by ARB staff and consultants. For example, Shlomo Castell, a Delta 747-400 pilot and the only commercial pilot who was a member of the CAC, asked that the consultants request bird strike information from the FAA and study it prior to submitting the draft Environmental Assessment, since he himself had experienced a bird strike and since there is a substantial Canada goose population at and around ARB. However, ARB's consultants ignored that request. In the end, the CAC did not come up with any recommendations or findings to be presented to ARB's consultants. Instead, it operated solely as a method for ARB's consultants to disseminate propaganda about the importance of the expansion, while giving the FAA, MDOT, and the City the cover they needed to state that they were providing "public participation."[11]

The other avenue for the public to influence ARB's and MDOT's decision was through the AAC. But the AAC is also heavily weighted in favor of ARB's interests. Although both Pittsfield and Lodi Township have "*ex officio*" members on the AAC, they have no voting power, and the Mayor of Ann Arbor appoints the remaining members. Even if Pittsfield and/or Lodi Township did have voting powers, the AAC has no decision-making authority, and can only recommend actions be taken. During the period in between the FAA's Initial Notice and the publication of the draft EA, the AAC met five times. However, the AAC also limits the time that the public can speak to only three minutes. Thus, it was impossible for the AAC to receive all of the information it needed to make well-reasoned decisions and recommendations with respect to the extension of Runway 6/24 at ARB.

[11] In fact, public access to the CAC was so limited and tightly controlled that Mr. Castell was falsely accused of using his laptop to record the CAC meeting and broadcast it over Skype, which the rules of the CAC prohibited.

On March 19, 2010, the FAA issued its Notice of Availability of Draft Environmental Assessment concerning the expansion at ARB. Exhibit 14. The FAA's Notice of Availability indicated that written comments would be received by MDOT until 5:00 p.m. EST April 12, 2010. In addition, the FAA's Notice of Availability indicated that there would be a "public hearing to provide information on the draft EA and accept comments from the public" on March 31, 2010. However, the "public hearing" actually was a three-hour "open house" held during the dinner hour period between 4-7 pm, during which individuals could assemble and provide public comments in response to the Environmental Assessment. Local media announcements of the event (AnnArbor.com) encouraged citizens to send comment letters directly to the Airport Manager, rather than MDOT, until Petitioners intervened and requested that MDOT correct the process to restore a semblance of fairness. At the session itself, there was no dais of public officials impaneled to answer the public's numerous questions. There were no open, public statements with the media present. All testimony was given in private rooms to court reporters, to be forwarded to MDOT for later evaluation and, presumably, incorporation into the final EA.

That citizens, not public officials, needed to police the process was the ultimate insult to ensure any semblance of fairness and equity. Because this public hearing process was so restrictive, members of the public were effectively deprived of their due process rights under the 14th Amendment of the U.S. Constitution. Pittsfield and its citizens have not had an opportunity to speak in an open and fair forum for a reasonable amount of time in opposition to the extension of Runway 6/24 at ARB before a public body on an issue that directly impacted their physical and economic well-being. That is because, if the extension proposal goes forward, the Ann Arbor City Council generally restricts all outside speakers to three minutes, which is hardly an adequate time to offer an organized and coherent argument against such a complex proposition as an airport expansion. At the same time, city officials and their surrogates are afforded unlimited time to speak to the City Council to advocate in favor of the runway extension, in clear violation of due process protections. Thus, by closing off the fairness and balance intended by holding this only federally-mandated forum, ARB and MDOT were able to stifle the only open public commentary and dissent regarding the airport in violation of the law.

Both Pittsfield and CPCQ submitted comments to the draft EA on April 19, 2010,[12] outlining in great detail the inadequacy of the draft EA and the need for a proper Environmental Impact Statement instead of an Environmental Assessment. *See* Exhibits 15 and 16. The Washtenaw County Water Commissioner also submitted comments to the draft EA, expressing serious concerns regarding inaccurate statements and the failure of the draft EA to address critical water resources issues with respect to the proposed project. Exhibit 17.

The Washtenaw County Water Commissioner was not alone is having reservations about the Project. On May 13, 2010, the Federal Aviation Administration also submitted comprehensive comments on the draft EA, raising a whole host of serious issues that the draft EA left unaddressed. *See* Exhibit 18. In particular, the FAA expresses its doubts of the Project's qualifying as a "safety" project, when the draft EA does not present any evidence for the need for the safety improvements detailed in the draft EA. These relate to the shifting of the runway 150 feet to the southwest so that sight lines between the Air Traffic Control Tower and the aircraft on the taxiway could be improved as well as allowing for the implementation of 34:1 approach instead of the current 20:1 approach. In its November 15, 2010, response, MDOT seems to abandon all of the safety improvements to the airport as being part of the "purpose and need,"

[12] MDOT and FAA extended the comment period from April 12, 2010, until April 19, 2010.

while still maintaining that 950 feet of impervious surface needs to be added to the southwest end of the Runway 6/24. *See* Exhibit 19.

The issue of lighting at ARB also raised FAA's concern. Since the FAA owns and controls the lighting at ARB, the relocation or replacement of the current approach lighting system as well as the development for future approach procedures for the new runway end locations is solely a federal action not within the scope of MDOT's block grant authority. Yet, the FAA points out, the draft EA fails to cover the environmental impact of the relocation and/or replacement of the approach lighting would have. Exhibit 18, p.1. Because of this fact, an additional environmental assessment has been ordered, but has yet to be completed.

Finally, the FAA requested that additional information be submitted regarding the number of critical aircraft using ARB and how ARB arrived at its conclusion that there were over 500 itinerant operations of the critical aircraft at ARB to justify the extension of the runway. The FAA concluded its comments by stating:

> Since there are several updates/clarifications requested by the FAA contained in this letter and the sponsor's responses may be substantial, it would be prudent to afford the public an additional opportunity to review and comment on the changes that are anticipated to be made for the final draft publication. Most specifically, the document will need to clearly outline the requested local, state and federal actions. Since this was not clearly presented in the initial draft EA, the FAA may consider these changes and clarifications as a material change to the document that should result in solicitation of additional public comment.

Exhibit 18, p.9.

But the story does not end there. There is a growing lack of support by the Ann Arbor City Council for the extension of the runway. The Ann Arbor City Council has removed ARB's expansion project from its Capital Improvement Project list for both 2011 and 2012. In addition, despite the fact that the City's portion of additional consulting work to be performed amounts to the relatively small sum of $1,125, the resolutions approving these expenditures were met with considerable skepticism and opposition by the City Council on the utility of the expansion. One City councilman remarked that he would "vote no on everything. It's taxpayer dollars, whether it's local or federal." Exhibit 20. He continued, stating that his constituents do not want the runway extension and he would vote no on that, too. *Id*. Another Council member allowed that the city's portion of the bill was very small but "what the council would be doing is spending money on something that won't move forward" reiterating the fact that the City Council had removed the project from the CIP, which, the Council member said, "translated into a decision that the council wouldn't move forward [with the extension of the runway]." *Id.*

II. LEGAL BASIS FOR PETITION

A. Statutory Basis for Pittsfield Petitioning the Secretary of Transportation.

Federal law gives communities[13] the right to petition the Secretary of Transportation about proposed airport development projects in their communities. 49 U.S.C. § 47106(c)(1)(A)(ii), states in pertinent part, that:

> (1) The Secretary [of Transportation] may approve an application under this subchapter [49 U.S.C. §§ 47101 *et seq.*] for an airport development project involving the location of an airport or runway or a major runway extension –
>
> (A) only if the sponsor certifies to the Secretary that –
>
> . . . .
>
> (ii) the airport management board has voting representation from the communities in which the project is located *or* has advised the communities that they have the right to petition the Secretary *about* a proposed project[14] . . . .

---

[13] Federal law does not define the term "communities." Thus, for purposes of this petition, Petitioners consider both Pittsfield and CPCQ to have standing to petition the Secretary of Transportation under federal law since they are both community organizations.

[14] This does not mean that the right to petition the Secretary does not exist for "communities" that have voting representation on the airport management board, only that the sponsor is not required to certify that it advised such communities that they have a right to petition the Secretary.

49 U.S.C. § 47106(c) (emphasis added). Congress, as part of the Airport and Airway Safety, Capacity, Noise Improvement, and Intermodal Transportation Act of 1992 (Pub. L. 102-581), added subsection (A)(ii) stating "the sponsor of the project certifies to the Secretary that the airport management board either has voting representation from the communities where the project is located or has advised the communities that they have the right to petition the Secretary concerning a proposed project."

The provision, however, is somewhat of an anomaly, since the provision itself does not give the communities the right to "petition the secretary," it states instead that prior to receiving approval of a grant for an "airport or runway or a major runway expansion," the sponsor must advise the communities of their right to petition the secretary "about a proposed project." This provision implies that the statutory "right to petition the secretary" exists beyond the scope of the paragraph, although it is the legal duty of the airport sponsor to inform "the communities" of their statutory right to petition the Secretary regarding the project *prior* to the sponsor receiving funding for the project. That is, this paragraph does not give the communities the right to petition the Secretary, but instead only requires that the sponsor certify that it has informed the communities of that pre-existing right. Thus, the communities' right to petition the Secretary of Transportation is separate from the sponsor's duty to inform the communities of that right.

Moreover, the paragraph also implies that the content of the petition need not solely concern environmental matters. Although the paragraph is entitled "Environmental Requirements," as explained above, the *right* to petition the Secretary exists separate and apart from the sponsor's duty to inform "the communities" of that right as part of the "Environmental Requirements." Indeed, one of the few cases to pass judgment on this statutory provision came to a similar conclusion. In *Communities Against Runway Expansion, Inc. et al. v. Federal Aviation*

Administration, 355 F.3d 678, 689 (D.C. Cir. 2004), the U.S. Circuit Court of Appeals for the District of Columbia held that 49 U.S.C. § 47106(c)(1)(A)(ii) was part of the grant application procedure, not the environmental procedure. On that basis the court rejected petitioners' claim that the Environmental Impact Statement was inadequate because the EIS failed to inform the communities of their right to petition the Secretary of Transportation. Thus, the scope of the petition to the Secretary goes beyond mere environmental analysis and extends to all reasons and issues why a proposed project should or should not be undertaken.

In addition, implicit in the language of the paragraph is the scope of the projects about which "communities" have a right to petition the Secretary. Although the statute states that the sponsor need only certify to the Secretary that "the communities" have been informed of their right to petition the Secretary for airport development projects that involve "the location of an airport or runway or a major extension," the paragraph states that the communities' right to petition extends to "a proposed project." The preceding clause in the paragraph states the certification is not necessary if the "airport management board has voting representation from the communities in which *the* project is located …" 49 U.S.C. § 47106(c)(1)(A)(ii)(emphasis added) *compare* "… has advised the communities that they have the right to petition the Secretary about *a* proposed project" (emphasis added). Had Congress intended that the right to petition the Secretary only extend to projects "involving the location of an airport or runway or a major runway extension," it would have used the definite pronoun "the" to indicate the project that is the "location of an airport or runway or a major extension." Instead, Congress uses the indefinite pronoun "a" coupled with the further distinction "proposed" to indicate a wider category of airport development projects. Thus, Congress must have meant to make a distinction between "in which the project is located" and "about a proposed project." And that distinction can only be that the right to petition the Secretary goes beyond limiting factors expressed in (c)(1).

B. Constitutional and Administrative Procedure Act Bases for Petition.

In addition to the provisions of the Airport and Airway Safety, Capacity, Noise Improvement, and Intermodal Transportation Act of 1992, the United States Constitution and the Administrative Procedures Act also give Petitioners a basis for petitioning the Secretary. The First Amendment of the U.S. Constitution states that "Congress shall make no law . . . abridging . . . the right of the people . . . to petition Government for a redress of grievances." U.S. Const., amend. 1. This right has been upheld numerous times by the courts. The right to petition for redress of grievances is among the most precious of the liberties safeguarded by the Bill of Rights. *United Mine Workers of America, Dist. 12 v. Illinois State Bar Association*, 389 U.S. 217, 222 (1967). It shares the "preferred place" accorded in our system of government to the First Amendment freedoms, and has "a sanctity and a sanction not permitting dubious intrusions." *Thomas v. Collins*, 323 U.S. 516, 530 (1945). "Any attempt to restrict those First Amendment liberties must be justified by clear public interest, threatened not doubtful or remotely, but by clear and present danger." *Id*. The Supreme Court has recognized that the right to petition is logically implicit in, and fundamental to, the very idea of a republican form of government. *United States v. Cruikshank*, 92 U.S. (2 Otto) 542, 552 (1875).

The purposes of the Administrative Procedure Act (5 U.S.C. § 551 *et seq.*) have been generally described as (1) to require agencies to keep the public informed of their organization, procedures and rules; (2) to provide for public participation in the rulemaking process; (3) to establish uniform standards for the conduct of formal rulemaking and adjudication; and (4) to define the scope of judicial review. Since this petition falls within the definition of "rule making" (5 U.S.C. § 551), the Administrative Procedure Act applies to the extent that Airport and Airway Safety, Capacity, Noise Improvement, and Intermodal Transportation Act of 1992 lacks clear direction.

III. NEITHER MDOT NOR THE FAA HAS GIVEN THE COMMUNITIES' INTEREST "FAIR CONSIDERATION" AS REQUIRED UNDER FEDERAL LAW.

The aviation statutes of the United States make it incumbent on the Federal Aviation Administration to ensure that communities are given the opportunity to express their frustration with a process that has explicitly disenfranchised them. *See* 49 U.S.C. § 47106(b)(2). That statute requires that before any federal funding of an airport development project takes place, the "Secretary must be satisfied that …the interests of the community in or near which the project may be located have been given fair consideration." 49 U.S.C. § 47106(b)(2). Thus, Petitioners ask federal intervention to preserve their due process rights, since local government has been afforded no voice in the ultimate decision as to whether the Project proceeds within Pittsfield's jurisdiction.

A. The Expansion at Ann Arbor Municipal Airport Does Not Comply With Planning in the Surrounding Communities.

The FAA has a duty under the law to ensure that federal funds are used properly for airport development projects that are required to fulfill the FAA's mission. Because of the substantial authority given to the Secretary of Transportation by Congress with respect to the development of airports, it is absolutely imperative that the concerns and issues of the surrounding communities are taken into account *prior* to approval of a project. This policy is reflected not only in the statutes that the FAA is bound to uphold, but in its regulations and guidance documents that it has issued. One place this policy is shown is in the assurances that airport sponsors, owners and operators are bound to follow upon accepting federal funds for airport development. In particular, grant assurances 6 and 7 state:

> 6. Consistency with Local Plans. The project is reasonably consistent with plans (existing at the time of submission of this application) of public agencies that are authorized by the State in which the project is located to plan for the development of the area surrounding the airport.
>
> 7. Consideration of Local Interest. It has given fair consideration to the interest of communities in or near where the project may be located.

FAA Airport Sponsor Grant Assurances, Exhibit 21. Thus, approval of this project without the approval by Petitioners would be a violation of ARB's grant assurances.

B. The City's Goals Are Not the Same as Petitioners' Goals.

While Petitioners recognize the safety concerns presented in the draft EA, they are less sympathetic with growth inducing aspects of the project which would subject both the government of Pittsfield and the people of Pittsfield to untold potential future damage. This damage would come in the form of both safety risks and in economic loss because of repeated flights of low flying, heavy jet aircraft. Pittsfield and its residents would have no choice but to seek recovery in the event of a tragic accident or inverse condemnation class action proceedings, from the City potentially leaving Pittsfield victims without an effective remedy at law.

1. The Project would increase safety concerns of low-flying aircraft near surrounding densely populated communities.

Petitioners would be subjected to a perfect storm of potential risks from low-flying aircraft in heavily populated neighborhoods that are also occupied by wildlife, including many Canada geese, during much of the year. *See* Exhibit 22 for map of ponds surrounding the airport that support Canada Geese. This is confirmed by a study conducted by MDOT and Ann Arbor's own airport architects (URS Corporation), which was excluded from the draft EA, and visualized on a projection of what the approach to an expanded Runway 6 would look like relative to the close proximity to area homes, which was corrected for accuracy. Exhibit 23.

The safety of having an airport so close to a densely populated area is not an unfounded fear. In June, 2009, a small single-engine plane attempting to land at ARB instead made an emergency landing 1,200 yards short of Runway 6/24 on a Stonebridge Golf Club fairway in Pittsfield after its engine died at low altitude on final approach. Exhibit 24. The pilot said if there had been people on the fairway at the time, he would have "crashed into the trees," which would have probably been fatal for him and his grandson, whom he was instructing at the time. *Id*. Moreover, it is not insignificant that between 1973 and 2001 nine people died from accidents flying in the Ann Arbor Airport traffic pattern within three miles of the airport. Exhibit 25. With Runway 6/24 extended 950 feet farther to the southwest and even closer to hundreds of homes, as proposed, and planes still lower on approach – and planes heavier, larger, carrying greater payloads, and more people – this poses a risk too grave to bring to a heavily populated community as well as to the users of ARB.

2. As a result of the Project ARB will attract more and heavier aircraft, which will increase the safety risk to the surrounding community as well lower their property values.

Extending Runway 6/24 by 950 feet will attract more and heavier jets (as well as larger multi-engine aircraft) while bringing them closer to heavily populated residential areas. ARB estimates that jets would be within 600 yards at altitudes of 93 feet above rooftops of homes, or lower, on a regular basis. Aircraft landing on Runway 6 would pass Lohr Road below 90 feet, which is the site of a new, planned non-motorized bike path, designated the Lohr-Textile Greenway Project, for which the Washtenaw County Parks and Recreation Commission has awarded Pittsfield a $300,000 Connecting Communities grant. Thus, low-flying, heavy jets would be landing just feet over people traversing a new non-motorized trail.

This is especially dangerous with heavier aircraft because, in the event of any common multi-engine aircraft mishaps – such as an engine failure on takeoff, a bird strike on takeoff, climb out, or approach, or similar incident – with aircraft in very close proximity to homes, the risk could be grave – a perfect storm of environmental or human risk. For example, a twin-engine jet losing one of its engines would lose 80 percent of its climb performance. At low altitudes that could be tragic. Likewise, the loss of an engine in a light twin-engine aircraft would be catastrophic, since the aircraft would not be able to continue to climb on one engine in takeoff configuration. Neither could it turn back toward the airport at low altitude in takeoff configuration.

Such impacts and safety implications on political jurisdictions where airports are located and where the airport decision-making bodies are devoid of local citizens and local governments must be investigated carefully and thoroughly by the governmental entities empowered to protect the safety of all concerned. The Department of Transportation and the FAA must protect the health and well-being of the people on the ground as well as those in the air from the inherent risks of aviation.

IV. THERE IS NO AVIATION SAFETY NEED TO EXTEND RUNWAY 6/24 AT ANN ARBOR MUNICIPAL AIRPORT BY 950 FEET.

The draft EA and the initial statements by ARB and MDOT tend to indicate that the primary purpose of the Project is to increase the safety at ARB. While parts of the Project may, in fact, contribute to an increase in aviation safety at ARB, the extension of Runway 6/24 will not provide any more safety either to those using the airport or to those on the ground.

A. Not All Alternatives That Would Meet the Stated Objectives for the Airport, Yet Still Meet the Stated Objectives and Goals, Were Considered.

As part of the National Environmental Policy Act ("NEPA") (42 U.S.C. §§ 4321 et seq.) process, federal agencies are required to examine all reasonable alternatives in preparing environmental documents. 42 U.S.C. § 4332(c)(iii). An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action is intended to address. The Council on Environmental Quality ("CEQ") Regulations ("NEPA Regulations"), which implement NEPA, require that Federal agencies "[u]se the NEPA process to identify and assess the reasonable alternatives to the proposed actions that will avoid or minimize adverse effects of these actions upon the quality of the human environment" 40 C.F.R. § 1500.2(e), and that "agencies shall . . . (a) Rigorously explore and objectively evaluate all reasonable alternatives . . ." 40 C.F.R. § 1502.14(a). The Project, as presented by ARB, has failed to explore all reasonable alternatives to the Preferred Alternative selected.

1. The draft EA utterly fails to give proper consideration to all reasonable alternatives.

The draft EA on p. 2-5 lists five objectives of the proposed project:

- Enhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions.

- Enhance operational safety by improving the FAA ATCT line-of-sight issues.

- Enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road.

- Reduce the occurrence of runway overrun incidents by small category A-I aircraft (local objective).

- Relocate and potentially upgrade the Runway 24 Approach Light System.

Exhibit 26, p. 2-5. To that end, ARB and MDOT dismissed out of hand the alternatives of "use other airports," "construct new airport," and "extend runway to the east." While Petitioners may agree that constructing a new airport and extending the runway to the east may not be feasible either economically or practically, the alternative "use other airports" should have been given more consideration. In particular, Willow Run Airport (YIP), as the draft EA notes "is capable of accommodating any of the aircraft that currently fly into ARB" and that it is located a mere 12 miles from ARB, or 20 minutes by surface transportation. But because some corporate magnates want to be able to fly in on their corporate jets to be 12 miles closer to their offices, federal taxpayers will have to expend millions of dollars on extending the runway at ARB. Moreover, ARB and MDOT imply that interstate commerce will be "enhanced" by the extension of the runway, when, in fact, it will take business away from Willow Run Airport – which already has the infrastructure and excess capacity in place to accept the larger aircraft that ARB so desperately desires.

The FAA reached the conclusion that some of the alternatives mentioned in the draft EA were not given a complete treatment. For example, the FAA stated that: "[b]ased on the information presented in the draft EA, the FAA has not reached the same conclusion that alternatives 1 and 2 do not meet the stated needs for the project."[15] Exhibit 18, p.7. If that is the case, then the draft EA must examine the environmental impacts of alternatives 1 and 2. Moreover, the FAA pointed out "[a]dditional alternatives that may be considered for evaluation to address the need statements could include a combination of items such as: alternative modes of transportation to address enhancing interstate commerce, removal or relocation of obstructions

---

[15] *See also* "… table [3-1] appears to incorrectly dismiss alternative 1 because it does not meet purpose and need. The discussion in 3.3.2 does not support that conclusion." Exhibit 18, p.7.

that limit ATCT line of sight issues, and raising or constructing a new ATCT to address the line of sight issues." *Id.*

2. Even after ARB and MDOT changed the need for the Project after the draft EA was published, they have failed to consider all reasonable alternatives.

However, in response to the FAA's comments, ARB and MDOT jettison their concern for the line-of-sight issue and the need for a 34:1 approach on the east end. MDOT and ARB, in their response to the FAA, specifically state that "[t]here is currently not a 'need' for the 34:1 approach." Exhibit 19, p.10. Indeed, ARB and MDOT restate the need in the November 15, 2010, letter as being "based on the objective of providing a primary runway of suitable length to safely accommodate critical category aircraft without operational weight restrictions." *Id.,* p.8. If that is the case – then Build Alternative 2, extending the existing runway 800 feet to the west (instead of 950 feet), should have been more fully examined in the environmental assessment. According to the draft EA Build Alternative 2 was rejected for further consideration because "[k]eeping the east runway end in its current location would not address the tower line of sight issue or the need for a 34:1 approach on the east end." Exhibit 26, p.3-9. The draft EA is not sufficient if the need purposed is simply providing "a primary runway of suitable length," since it failed to assess properly the environmental impacts of Build Alternative 2. In addition, if the need is simply to provide "a primary runway of suitable length," ARB and MDOT have not yet shown that the need cannot be met by using Willow Run Airport instead of ARB.

On the other hand, if the tower line of sight issue or the need for a 34:1 approach on the east end are, indeed, issues that should be addressed, then ARB and MDOT have failed to take into account yet another alternative. The "need" to address the tower line of sight issue and the "need" for a 34:1 approach on the east end could be met by simply shifting Runway 6/24 150 feet to the southwest, *i.e.*, removing 150 feet from the approach end of Runway 24 and adding 150 feet to the departure end of Runway 24. Runway length would remain 3,505 feet.

Section 2.2.1 of the draft EA states that a 150-foot shift of the Runway 24 threshold to the west would (1) enhance the safety of ground operations by taxiing aircraft; (2) enhance operational safety, and possibly prevent runway incursions, by expanding the view of the hold area and parallel taxiway to ATCT personnel; (3) allow for a clear 34:1 approach surface to the east end of the runway, providing an added margin of safety between approaching aircraft and ground-based obstacles, which is particularly beneficial when aircraft are operating in low-visibility conditions; and (4) include relocation and replacement of the existing runway approach light system with newer Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF). Exhibit 26. Shifting Runway 6/24 150 feet to the Southwest without lengthening the runway would also accommodate future widening of State Road. Nevertheless, this "reasonable alternative" was not considered in the draft EA. An Environmental Assessment "shall include brief discussions of . . . alternatives . . ." 40 C.F.R. § 1508.9(b).1. Absent an analysis of an alternative based on a 150-foot southwesterly shift of the runway, without lengthening the runway, the EA is inadequate and the Project should not be approved.

B. Resolving ARB and MDOT's "Need" Through the Extension of Runway 6/24 Is Unsupported by the Evidence.

An Environmental Assessment must include a discussion of the purpose and need for the proposed action that must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." 40 C.F.R. § 1502.13. In addressing the "purpose and need" section of an EA, FAA Order 1050.1E provides that: "[t]his discussion identifies the problem facing the proponent (that is, the need for an action), the purpose of the action (that is, the proposed solution to the problem), and the proposed timeframe for implementing the action." FAA Order 1050.1E, ¶ 405c. The draft EA accomplishes none of these goals and ARB and MDOT have not discussed or examined what exactly the need for the Project is. Although the draft EA never specifies the need for the Project, it does identify the purpose along with various "objectives." *See supra* pp.25 – 26.

1. The Project is not supported by any reasonable and independent evidence and does not solve the problem it purports to solve.

First, the draft EA defines the purpose of the Project as "to provide facilities that more effectively and efficiently accommodate the critical aircraft that presently use the airport, as well as to enhance the operational safety of the airport." Exhibit 26. After being taken to task by the FAA for its lack of a clear definition of a "need" in the draft EA, ARB and MDOT responded that the need (although nowhere to be found in the draft EA) "for the project is based on the objective of providing a primary runway of suitable length to safely accommodate critical category aircraft without operational weight restrictions."[16] Exhibit 19, p.8. The draft EA defines "critical aircraft" as "the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport," and claims that a 2009 MDOT Airport User Survey "has confirmed that the critical aircraft classification for ARB is 'B-II Small Aircraft.'" Exhibit 26, p.2-4. To effectuate the stated purpose, the draft EA purports to support the construction of a runway extension from 3,505 feet to 4,300 feet. However, the evidence is clear that no "B-II Small Aircraft" require a 4,300 foot long runway. All B-II Small Aircraft are capable of operating on the existing 3,505 feet long runway without weight restriction. In fact, the representative B-II Small Aircraft cited by ARB as justification for the Project, the Beechcraft King Air 200, requires only 2,579 feet of runway to take-off fully loaded, and 2,845 feet to land.

[16] As defined by the FAA in FAA Order 1050.1E, ¶ 405c, this is not a "need" but simply a restatement of the purpose. ARB and MDOT have yet to identify and discuss in any reasonable manner "the problem facing the proponent."

See, http://www.hawkerbeechcraft.com/beechcraft/king_airb200gt/specifications.aspx. Thus, the statement that "[d]evelopment of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small Aircraft to operate at their optimum capabilities (without weight restrictions)," although true, is misleading. Exhibit 26.

There is no need to extend Runway 6/24 to allow B-II aircraft to operate at ARB. They can operate on a 3,505 foot runway without weight restrictions. Therefore, the statement that interstate commerce would be negatively impacted by B-II weight restrictions does not state a valid need, and the purported purpose of "provid[ing] facilities that more effectively and efficiently accommodate the critical aircraft that presently use the airport" is an unnecessary solution to a nonexistent problem.

2. ARB's justification for the Project incorrectly relies on total annual operations to support extending Runway 6/24.

The draft EA states, "[t]he critical aircraft, or grouping of aircraft are generally the largest, most demanding types that conduct at least 500 operations per year at the airport," and concludes that the proper Airport Reference Code ("ARC") for ARB is B-II, based on a total of "750 actual annual operations by B-II category critical aircraft from survey data year 2007." Exhibit 26. However, the draft EA's use of "annual operations" differs markedly from the FAA criteria for selecting runway lengths and widths set forth in FAA Order 5090.3C:

> 3-4. AIRPORT DIMENSIONAL STANDARDS
>
> Airport dimensional standards (such as runway length and width, separation standards, surface gradients, etc.) should be selected which are appropriate for the critical aircraft that will make substantial use of the airport in the planning period. Substantial use means either 500 or more *annual itinerant operations*, or scheduled commercial service.

FAA Order 5090.3C, p. 21 (emphasis added). It should be pointed out that FAA Order 5090.3C does not state that critical aircraft must be the "largest." The FAA divides General Aviation operations into two categories, “local” and “itinerant.” Itinerant operations are defined as “an operation performed by an aircraft, either IFR, SVFR, or VFR, that lands at an airport, arriving from outside the airport area, or departs an airport and leaves the airport area.” U.S. DOT JO 7210.695, p.5. Local operations are defined as “those operations performed by aircraft that remain in the local traffic pattern, execute simulated instrument approaches or low passes at the airport, and the operations to or from the airport and a designated practice area within a 20-mile radius of the tower.” *Id*.

The draft EA, without reference to this distinction, relies on “annual operations” and “total annual operations” not “itinerant operations.” *See* Exhibit 26, Table 2-1, p. 2-10. Separating itinerant and local operations at ARB would result in a dramatic reduction in the number of annual critical aircraft operations at the airport. For example, data from the website City-Data.com shows that there were 25,064 itinerant operations and 44,174 local operations at ARB in 2008. *See*, http://www.city-data.com/airports/Ann-Arbor-Michigan.html. In that itinerant operations account for approximately 36% of the total operations at ARB, itinerant B-II operations for 2007 would be in the neighborhood of 300 operations per year (40% of 750 total operations), substantially below the FAA’s threshold of 500 annual operations to constitute “substantial use.” Moreover, the Airport User Survey shows only 293 annual B-II operations at ARB in 2007. Thus, the FAA Order 5090.3C airport dimensional standards for B-II small aircraft do not apply.

Even if, for argument’s sake, we were to accept the critical aircraft data reported in the Airport User Survey, a detailed analysis shows that a weighted average of 78 percent of those B-II aircraft operations took place within a 450-mile radius of ARB, according to MDOT’s own data analysis. Exhibit 27. These represent areas that are within the flight range of ARB’s current based fleet, according to the User Survey data, from the current-length runway. Thus, by another means of calculus, itinerant operations beyond the range of need are fewer than 200 and the Purpose and Need fails.

Further, MDOT's choice of 2007 as a year of certification for critical aircraft was based on an arbitrary and capricious decision. The year 2007 represents the greatest number of ARB operations in the 5-year period 2004-2009 and was selected, according to the MDOT analyst involved, because "our thoughts were that the current recession could possibly have affected the 2008 operational levels in such a way that 2008 year records would not be a true indicator of a post-recession return to normal operations at the airport. . .." Exhibit 26. Even the FAA suggests ARB will not return to such high operating levels as 2007 for the next 20 years. Thus, MDOT was showing bias and affording Ann Arbor a huge advantage in not even evaluating operational data from any other year, particularly one that is more recent than 2007. Objectively, since its standard is the independent FlightAware data base, MDOT should analyze critical aircraft operational data for the five years 2007-2012 and base its decision on an average of those years' operational data. However, such aircraft operational data should be (1) independent, (2) verifiable, and (3) operationally detailed.

At the FAA's request, ARB examined the aircraft operational data for 2009. However, despite ARB and MDOT's claim that "there were still over 500 annual itinerant operations conducted by category B-II at ARB in 2009" (Exhibit 19, p.13), the data provided by ARB and MDOT could only support 346 critical aircraft (not necessarily itinerant) flights. These were the only flights that were (1) independent, (2) verifiable, and (3) operationally detailed, since they were derived from the FlightAware database. Since this is a critical issue, only operational data meeting these criteria should be used. MDOT's analyst, however, allowed purported additional critical aircraft flights (again, not necessarily itinerant flights) based on a corporate pilot's one-line letter certification. These flights were unsupported by the FlightAware data or other independent criteria. Because these flights are not verifiable, independent or operational detailed they must be excluded from the determination of the critical aircraft category at ARB.

3. Shifting Runway 6/24 150 Feet to the Southwest Will Not Achieve an Additional Margin of Safety.

The draft EA states that part of the Project's purpose is to "[e]nhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road." Exhibit 26. Operational safety in low visibility conditions will not be enhanced by providing a clear 34:1 approach surface to Runway 24. The draft EA is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel. Exhibit 26. However, in the next paragraph the draft EA states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles." Exhibit 26. This statement lacks support in either the Instrument Approach Procedure (IAP) design or Terminal Instrument Procedures ("TERPS") Obstruction Standards. Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP, and are defined as "Obstacle Identification Surfaces," which do not establish obstacle clearance safety margins, but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety" as stated in the draft EA does not apply in the case of these two surfaces. Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions, and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the FAA to accommodate all existing obstructions. Thus, shifting the runway 150 feet to the west would not enhance safety. Even if one were to assume that the draft EA is correct in the assertion that shifting the Runway 24 threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement, but would result only in a reduction in the required approach visibility minimums. In its response to the FAA's comments, ARB and MDOT drop the shifting of Runway 6/24 as a "need."

4. ARB and MDOT falsely conveyed the impression that ARB is located in a rural setting instead of in a densely populated area.

The draft EA intends to deceive readers as to the cosmopolitan location of the airport, utilizing Figure 2.1, for instance, which depicts unpaved Lohr and Textile Roads and vacant land and rock pits and gravel pits where developed communities of Pittsfield (Brian Hill, Lake Forest, Lake Forest Highlands, Lohr Lakes Village, St. James Woods, Silo Ridge, Stonebridge, and Waterways) and Lodi (Travis Pointe) Townships exist today, with more than 2,000 homes – making the area appear far more rural and not susceptible to the safety risks from added airport development that are actually posed.

V. THE EXTENSION OF THE RUNWAY WILL CAUSE SIGNIFICANT ENVIRONMENTAL IMPACTS ON THE SURROUNDING COMMUNITIES.

United States federal law states at 49 U.S.C. § 47101(a)(6) that it is "the policy of the United States - - that airport development under this subchapter provide for the protection and enhancement of natural resources and the quality of the environment of the United States." The Project will have a significant impact on the environment not only on the airport, but throughout the surrounding community. Since it is Pittsfield's duty and responsibility to protect the environment within its boundaries and protect its citizens from significant environmental impacts, it has serious concerns about the environmental impact the Project will have on the community.

A. The Data Used to Justify the Project Is Not Current.

Even when the draft EA first came out almost three years ago, Petitioners had issues about the timeliness of the data presented. The data that the Airport relied upon was almost three years old when it was used in the draft EA.

Moreover, it is the FAA's policy to use timely data instead of data that is stale, like the data used to justify the Project. In particular, ¶ 402a of FAA Order 1050.1E states that

> A draft EA may be assumed valid for a period of three years. If the approving official has not issued an EA/FONSI within three years of receipt of the final draft EA, a written reevaluation of the draft (see paragraph 410) must be prepared by the responsible FAA official to determine whether the consideration of alternatives, impacts, existing environment, and mitigation measures set forth in the EA remain applicable, accurate, and valid. If there have been changes in these factors that would be significant in the consideration of the proposal, a supplement to the EA or a new EA must be prepared in accordance with the procedures of this chapter.

FAA Order 1050.1E. Although it has not yet been three years since MDOT issued the draft EA, at the very least a written re-evaluation must be issued, particularly since the data used in the draft EA was stale when the draft EA was first issued.

B. The Project Does Not Take into Account the Noise Impact of the Project on the Surrounding Community.

It has long been "the policy of the United States - - that aviation facilities be constructed and operated to minimize current and projected noise impact on nearby communities." 49 U.S.C. § 47101(a)(2). Part of the FAA's mission is to ensure that the communities surrounding airports are not adversely impacted by noise from aircraft at airports. This mission is expressed in 49 U.S.C. § 47101(c), which states that "[i]t is in the public interest to recognize the effects of airport capacity expansion projects on aircraft noise. Efforts to increase capacity through any means can have an impact on surrounding communities. Noncompatible land uses around airports must be reduced and efforts to mitigate noise must be given a high priority." Thus, to the extent that noncompatible land uses around airports cannot be reduced, then the capacity of nearby airports should not be increased or else the FAA and the airport sponsor would be in violation of federal law. ARB and MDOT seem to be aware of the fact that increases in capacity at the airport will affect the noise levels in Pittsfield, because they studiously avoid the topic.

1. ARB and MDOT incorrectly assume that extending the runway will not increase the number of air operations, the fleet mix or other growth-inducing effects of the Project.

When considering an airport project for federal funding, the FAA is required to evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project (40 C.F.R. § 1508.8(b)) as well as increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). The "growth-inducing effects of [an] airport project appear to be its *raison d'etre*." *California v. U.S. D.O.T.*, 260 F.Supp.2d at 978, citing *City of Davis*, *supra*, 521 F.2d at 675. Even though the Project is virtually defined by its growth-inducing impacts, ARB and MDOT have ignored this requirement completely – not only in the draft EA, but in the public participation aspects of the Project as well. Although ARB and MDOT claim that the "percent of night and jet operations would remain constant between the existing condition and the future years," there is substantial evidence to indicate that the Project will cause a large increase in both types of operations. Exhibit 26, p.4-2.

As indicated above, there are no weight restrictions that must be lifted to allow ARB's "critical aircraft" to operate at the airport without weight restrictions. For example, the "load restrictions" referenced on page 2-12 of the draft EA refer not to category B-II aircraft, but to the fact that higher category aircraft (jets in the C-I and C-II categories) must currently operate at reduced weights in order to use the current 3,505 foot runway. Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, all of which discourage these aircraft from conducting operations at ARB. A Cessna Citation II (Category B-II), for example, requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and can operate at unrestricted weight from the existing 3,505 foot runway. A Lear 35 (Category C-I), on the other hand, requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,300 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be less than is currently required. Therefore, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Citation jet, which the EA states is a "critical aircraft."

The primary reason why ARB and MDOT are so keen on extending the runway is to facilitate the loading of additional passengers and baggage on high performance jet aircraft outside of what ARB considers to be its "critical aircraft." Also, the ability to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. If the runway is lengthened to 4,300 feet, it is reasonably foreseeable that ARB will become much more attractive to operators of higher performance jet aircraft, such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II), who could then operate at ARB instead of driving to and from Willow Run Airport, a mere 12.3 mile car trip, where there are ample facilities for large aircraft.

2. The fact that night and jet operations will increase as a result of the Project has not been analyzed by either ARB or MDOT.

Contrary to ARB and MDOT's unsupported assertions in the draft EA (*see e.g.* Exhibit 26, p. 4-2; Appendix B-1, p. B-4), it is reasonably foreseeable that the fleet mix at ARB will change in favor of a higher percentage of jet operations as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft account for a high percentage of ARB operations. B-II aircraft account for a low percentage of ARB operations. Because of the availability of a longer runway, it is therefore reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer haul business jets often occur in the evening hours due to the longer time duration of their trips. Since one of the stated purposes of the Project is to increase interstate commerce, this is not merely an indirect, but also a direct effect, that the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Thus, the evidence is clear that the Project will cause an increase in both jet and night operations. It is also reasonably foreseeable that these added high-performance jet aircraft operations and night operations will be accompanied by significant noise and air quality impacts. Nevertheless, ARB and MDOT have failed to acknowledge, let alone analyze, these reasonably foreseeable impacts caused by expansion of airport physical facilities and operational profile and, thus, the Project should not be approved for federal funding.

3. Increased jet aircraft and nighttime operations were not included in the noise modeling used by ARB and MDOT.

The sole presentation of the noise modeling performed by ARB and MDOT is presented in the draft EA. On its face it is insufficient to meet FAA standards. The FAA's Integrated Noise Model (INM) was used to model annual operations for the 2009 existing condition in the draft EA, *i.e.*, April 2008 through March 2009 and develop 65, 70 and 75 DNL noise contours for the Project. Exhibit 26, Appendix B-1, p.4, p. 4-3. The EA states that "[t]he existing 65 DNL contour does not extend beyond airport property." Exhibit 26, p. 4-3. However, during the time modeled, jet operations accounted for approximately 2 percent of total operations at ARB, and nighttime operations accounted for 4.2 percent of total operations. Exhibit 26, p. 4-2. The draft EA states: (1) "[t]he percent of night and jet operations would remain constant between the existing condition and the future years;" (2) "fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives would remain static"; and (3) "[t]he ARB 2014 proposed project alternative DNL 65 dBA noise contour does not extend beyond airport property." Exhibit 26, p. 4-2; Appendix B-1, p. B-4; p. B-6.

None of these assertions are based on facts or the reality of the situation that exists at ARB. As shown above, because of the increase in the length of the runway the Project will likely facilitate an increased number of night operations, and a change in fleet mix that will include higher performance jet aircraft. DNL calculations depend on, among other things, forecast numbers of operations, operational fleet mix and times of operation (day versus night). Exhibit 26, Appendix B-2, p. B-16. However, ARB and MDOT have failed to model or assess future increased night operations and fleet mix changes resulting from the Project.

The FAA requires the use of INM to produce, among other things: (1) noise contours at the DNL 75 dB, DNL 70 dB and DNL 65 dB levels; (2) analysis within the proposed alternative

DNL 65 dB contour to identify noise sensitive areas where noise will increase by DNL 1.5 dB ; and (3) analysis within the DNL 60-65 dB contours to identify noise sensitive areas where noise will increase by DNL 3dB, if DNL 1.5 dB increases as documented within the DNL 65 dB contour. FAA Order 1050.1E, Appendix A, p. A-62, & 14.4d. As the noise modeling failed to take into account the foreseeable increases in nighttime and jet aircraft operations at ARB, the questions of whether the future DNL 65 dB contour will be increased, and to what extent, and whether increased noise levels within the DNL 65 dB contour would necessitate designation of a DNL 60 dB contour remain unanswered.

4. Noise from aircraft, particularly high performance jets, remains a very real concern for communities that surround ARB.

The FAA last reviewed the technical bases for its noise policies in 1992. For example, 65 DNL as the "threshold of significant impact" under NEPA and the level below which land uses are deemed compatible has been used by the FAA without substantial change since *1978* (it was "re-affirmed" by FICAN in 1992). It is safe to say that the FAA's policy no longer reflects the best scientific evidence of the effects of aircraft noise exposure. This failure on the part of the FAA to update its policy undermines the trust that the public places in the FAA in their pursuit to understand noise exposure and its effects.

This is particularly true since substantial research done on the measurement and effect of aircraft noise on the communities surrounding airports has come from sources outside the United States. For example, the Hypertension & Exposure to Noise Near Airports (HYENA) study evaluated the effects of aircraft noise on 4,861 persons residing near 7 European airports between 2002 and 2006. The 2002 RANCH study from London studied the effect of aircraft and road traffic noise on 2,844 children's cognition and health. Both of these studies came out with rather startling results concerning the effect aircraft noise has on the quality of human life.

Finally, WHO Europe issued "Night Noise Guidelines," which were based on research done by the European Union. This type of study has largely been absent in the United States.

The emerging research suggests that current standards used by the FAA are outdated and underestimate the significant health risks posed by aircraft noise. The current understanding of the health effects of aircraft noise goes beyond mere annoyance and sleep disturbance, which the current DNL protocols were meant to address. The new research shows a strong correlation between aircraft noise and significant, serious health outcomes, such as hypertension and heart disease. Four studies from Europe have shown this connection:

1. Haralabidis AS, Dimakopoulou K, Velonaki V, Barbaglia G, Mussin M, Giampaolo M, Selander J, Pershagen G, Dudley ML, Babisch W, Swart W, Katsouyanni K, Järup L; for the HYENA Consortium. Can exposure to noise affect the 24 h blood pressure profile? Results from the HYENA study. *J Epidemiol Community Health*. 2010 Jun 27.

2. Haralabidis AS, Dimakopoulou K, Vigna-Taglianti F, Giampaolo M, Borgini A, Dudley ML, Pershagen G, Bluhm G, Houthuijs D, Babisch W, Velonakis M, Katsouyanni K, Jarup L; for the HYENA Consortium. Acute effects of night-time noise exposure on blood pressure in populations living near airports. *Eur Heart J*. 2008 Feb 12

3. Jarup L, Babisch W, Houthuijs D, Pershagen G, Katsouyanni K, Cadum E, Dudley M-L, Savigny P, Seiffert I, Swart W, Breugelmans O, Bluhm G, Selander J, Haralabidis A, Dimakopoulou K, Sourtzi P, Velonakis M, VignaTaglianti F, on behalf of the HYENA study team. Hypertension and Exposure to Noise near Airports - the HYENA study. *Environ Health Perspect* 2008; 116:329-33

4. Jarup L, Dudley ML, Babisch W, Houthuijs D, Swart W, Pershagen G, Bluhm G, Katsouyanni K, Velonakis M, Cadum E, Vigna-Taglianti F for the HYENA Consortium. Hypertension and exposure to noise near airports (HYENA) - Study design and noise exposure assessment. *Environ Health Perspect* 2005; 113:1473-8.

This is not to say that there has not been any research done in the United States on this issue. In March 2007, for example, Lisa Goines and Louis Hagler published their article entitled "Noise

Pollution: A Modern Plague" in the *Southern Medical Journal*. While it did not concentrate solely on aircraft noise, the article concluded that

> [n]oise produces direct and cumulative adverse effects that impair health and that degrade residential, social, working, and learning environments with corresponding real (economic) and intangible (well-being) losses. It interferes with sleep, concentration, communication, and recreation. The aim of enlightened governmental controls should be to protect citizens from the adverse effects of airborne pollution, including those produced by noise. People have the right to choose the nature of their acoustical environment; it should not be imposed by others.

ARB and MDOT are imposing the nature of their "acoustical environment" on Pittsfield and its citizens, rather than having the citizens choosing for themselves.

In addition several "findings" have been issued by governmental or quasi-governmental sources. The Federal Interagency Committee on Aviation Noise (FICAN) has issued two findings: *FICAN Recommendation for use of ANSI Standard to Predict Awakenings from Aircraft Noise* (2008) and *Findings of the FICAN Pilot Study on the Relationship between Aircraft Noise Reduction and Changes in Standardized Test Scores* (2007). Partnership for AiR Transportation Noise and Emissions Reduction (PARTNER), a collaboration among the FAA, NASA and TransportCanada, issued in July 2010, its *Review of the Literature Related to Potential Health Effects of Aircraft Noise*, (prepared by Hales Swift). That review concluded that "[p]otentially serious health outcomes have been identified in studies involving transportation noise exposure in a population. These include heart disease and hypertension and the observed effects seem to be related especially to nighttime noise exposure although similar daytime exposure effects have also been identified." PARTNER 2010, p.62. PARTNER has also issued several other reports:

• Sonic Boom and Subsonic Aircraft Noise Outdoor Simulation Design Study. Victor W. Sparrow, Steven L. Garrett. A PARTNER Project 24 report. May 2010. Report No. PARTNER-COE-2010-002.

• Passive Sound Insulation: PARTNER Project 1.5 Report. Daniel H. Robinson, Robert J. Bernhard, Luc G. Mongeau. January 2008. Report No. PARTNER-COE-2008-003.

• Vibration and Rattle Mitigation: PARTNER Project 1.6 Report. Daniel H. Robinson, Robert J. Bernhard, Luc G. Mongeau. January 2008. Report No. PARTNER-COE-2008-004.

• Low Frequency Noise Study. Kathleen Hodgdon, Anthony Atchley, Robert Bernhard. April 2007. (Report No. PARTNER-COE-2007-001) PARTNER Project 1, Low Frequency Noise Study, final report.

• Land Use Management and Airport Controls: A further study of trends and indicators of incompatible land use. Kai Ming Li, Gary Eiff. September 2008. Report No. PARTNER-COE-2008-006

• En Route Traffic Optimization to Reduce Environmental Impact: PARTNER Project 5 Report. John-Paul Clarke, Marcus Lowther, Liling Ren, William Singhose, Senay Solak, Adan Vela, Lawrence Wong. July 2008. Report no. PARTNER-COE-2008-005

• Land Use Management and Airport Controls: Trends and indicators of incompatible land use. Kai Ming Li, Gary Eiff, John Laffitte, Dwayne McDaniel. December 2007. (Report No. PARTNER-COE-2008-001) PARTNER Project 6 final report.

Thus, there is no shortage of relevant, topical information for ARB, MDOT and the FAA to use in assessing the health risks and impacts of noise on the communities surrounding ARB. It is readily apparent that the current system does not fully account for the increased health risks communities surrounding airports are subject to due to the increased noise levels. FAA needs to re-evaluate its noise modeling and insist that health risks to the surrounding communities be assessed prior to ARB receiving federal funds for any expansion that will result in an increase in aviation operations.

C. ARB and MDOT Have Failed to Take Into Account the Effects the Project Will Have on Air Pollution in the Surrounding Community.

Section 7506 of the Federal Clean Air Act (42 U.S.C. § 7401 et seq.) mandates that "[n]o department, agency, or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to [a State Implementation Plan] after it has been approved or promulgated under [42 U.S.C. §7410]." The Environmental Protection Agency (EPA) has promulgated regulations implementing § 7506 (the "Conformity Provision") in 40 C.F.R. § 93.150 *et seq*. ("General Conformity Rule"). The General Conformity Rule requires, in part, that federal agencies first determine if a project is either exempt from conformity analysis or presumed to conform. If it is neither, the agency must conduct a conformity applicability analysis to determine if a full conformity determination is required. *See Air Quality Procedures for Civilian Airports and Air Force Bases*, p. 13.

The project area, *i.e.*, Washtenaw County, is in attainment for five of the seven criteria pollutants, and marginal nonattainment for Ozone. Exhibit 28. Washtenaw County is designated as in nonattainment for $PM_{2.5}$. *Id*. Therefore, one of the following applies:(1) the project is exempt from conformity; (2) the project is presumed to conform; or (3) the agency must conduct a conformity applicability analysis to determine if a conformity determination for $PM_{2.5}$ is required. Neither ARB nor MDOT has indicated that any of the required actions was performed.

The draft EA does not provide any guidance as to whether the Project is exempt or presumed to conform. At page C-4, the draft EA states unequivocally that "[f]or this analysis it will be assumed that the project is *neither* exempt nor presumed to conform." (Emphasis added). However, on the next page, the draft EA states that ". . . a conformity determination is not required and the proposed project *is presumed to conform* to the state implementation plan."

Exhibit 26, p.C-5, (emphasis added). Under either scenario, however, ARB and MDOT have failed to meet the "public disclosure" requirement under NEPA.

1. ARB and MDOT have failed to establish that the Project is exempt.

There are two options in determining that a project is exempt from conformity analysis: (1) if the project is included in the list of exempt actions listed in § 93.153(c)(2); or (2) if the project's total of direct and indirect emissions are below the emissions levels specified in § 95.153(b) of the Conformity Regulations ("*de minimis*"), § 93.153(c)(1).

The first option does not apply here because none of the actions to be undertaken as part of the Project are included as "exempt actions" § 93.153(c)(2). Exhibit 26, p. 2-1. Nor does the Project qualify as exempt because of *de minimis* emissions under 40 C.F.R. § 93.153(c)(1). The closest ARB and MDOT come to any type of air quality analysis can be found on pp. 4-17 and 4-18 of the draft EA. ARB and MDOT, instead of performing a site-relevant analysis, rely on an outdated study, 1996 MDOT Bureau of Aeronautics Air Quality Study of seven general aviation airports (which notably do not include ARB), to conclude that "typical GA airports generate a low level of pollutants." Exhibit 26, p. 4-17. From there, ARB and MDOT extrapolate that because ARB is comparable in size and activity to the seven airports studied, it can be assumed that emissions resulting from the Project will not exceed the conformity threshold levels, and, on that basis, concludes that a conformity analysis is not required.

This assumption, however, does not comply with federal law for at least two reasons. First, neither ARB nor MDOT has quantified $PM_{2.5}$ emissions from flight operations at ARB. Even the superannuated 1996 Study makes no mention of ARB. Second, because ARB and MDOT have failed to quantify the emissions, there can be no comparison with the *de minimis* thresholds established in 40 C.F.R. § 93.153(c)(1). While the original version of 40 C.F.R. §

93.153(c)(1) did not establish explicit thresholds for $PM_{2.5}$, as distinguished from PM_{10}, the newly implemented revised General Conformity Rule does establish that distinction, and now serves as the template for the air quality analysis required in the EA. Moreover, FAA Order 1050.1E, Appendix A, p. A3, § 2.16 includes both PM_{10} and $PM_{2.5}$ in "particulate matter."

2. ARB and MDOT have failed to establish that the project is "presumed to conform."

The second option, the presumption of conformity, does not apply here either. In order for a federal action to be "presumed to conform," the Project has to fall within a category of actions predetermined by the responsible federal agency to carry a presumption of conformity. *See* 40 C.F.R. § 93.154(f) – (h). In July, 2007, the FAA published its *Federal Presumed to Conform Actions Under General Conformity Final Notice*, 72 Fed.Reg. 41,565-580 (July 2007), in which the FAA listed fifteen Airport Project categories that the FAA presumes to conform to applicable SIPs. None of the actions to be undertaken by the Project fall within any of those presumed to conform categories. ARB and MDOT cannot unilaterally presume that the Project is in conformity and therefore the draft EA's statement is in error.

3. ARB and MDOT have failed to establish the Project's conformity status under the Clean Air Act.

Finally, the antiquated study of General Aviation airports in Michigan other than ARB is an inadequate substitute for the required analysis. 40 C.F.R. § 93.159 requires that analyses under the General Conformity Rule be based on, among other things: (1) "the latest planning assumptions" (§ 93.159(a)); and (2) "the latest and most accurate emissions estimation techniques available" (§ 93.159(b)). The 1996, 17-year old, study patently fails to fall within either, let alone both, of these parameters. In summary, the EA fails to establish the existence of any of the necessary components of the required finding of conformity for a project that can be supported by federal funds, and, thus, is inadequate under federal aviation statutes, NEPA and the Clean Air Act.

D. ARB and MDOT Have Failed to Take Into Account the Effect the Project Will Have on Water Resources in the Surrounding Communities.

Throughout this process ARB and MDOT have consistently understated the significance of water resources. The principal use of the grounds where the airport is located is for the collection and pumping of water for the City. However, water quality is something that must be taken much more seriously than ARB or MDOT has taken it. As FAA Order 1050.1E points out "[i]f there is the potential for contamination of an aquifer designated by the [EPA] as a sole or principal drinking water resource for the area, the responsible FAA official needs to consult with the EPA regional office, as required by section 1424(e) of the Safe Drinking Water Act, as amended." FAA Order 1050.1E, pp. A-74, 75, ¶ 17.1c. Likewise, "[w]hen the thresholds indicate that the potential exists for significant water quality impacts, additional analysis in consultation with State or Federal agencies responsible for protecting water quality will be necessary. *Id*., pp. A-75, A-76, ¶ 17.4a. Finally, in situations such as this, "[i]f the EA and early consultation [with the EPA] show that there is a potential for exceeding water quality standards [or] identify water quality problems that cannot be avoided or mitigated . . . an EIS may be required. *Id*., pp. A-75, ¶ 17.3.

The Airport is the location of a porous sand/gravel formation that yields a large amount of water for pumping. Historically, the land where the airport is located was originally acquired by the City of Ann Arbor for water rights in 1929. Until recently, 15% of Ann Arbor's water supply came from the three wells located on Airport property. Exhibit 29, Water Quality Report, 2008, City of Ann Arbor, p. 2. The paving that the Project will require increases not only the impervious area on top of the aquifer, but also increases the risk of contamination. This in turn reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer that is vital to the City. However, ARB and MDOT have given this issue only passing mention: "[b]ased on coordination with the City of Ann Arbor, the proposed runway extension would not impact the water supply wells or the new water supply line (Bahl, 2009)." Exhibit 26, p. 4-20. Notably absent from their coordination efforts is the EPA or its Regional Office with respect to water resource issues.

ARB and MDOT's nonchalance with respect to a principal source of Ann Arbor's water supply raised serious issues with the Washtenaw County Water Resources Commissioner – another entity with whom ARB and MDOT should have been consulting from the very beginning. In response to the draft EA, the Washtenaw County Water Resources Commissioner pointed out:

> It is noted in the [draft EA] that: "The amount of impervious surface on site would increase slightly due to the extension of the runway and taxiway from the existing 7 percent of the 837 acres to 7.4 percent." This slight increase noted equates to an additional 3.348 acres or 145,839 square feet. This increase in impervious surface is considered by this office to be significant and not slight particularly knowing that the additional runoff from this area will discharge to the Wood Outlet Drain.

Exhibit 17, p.2. This, coupled with the fact that the City owns and operates four water wells on ARB's property, causes deep concern with the County.

This issue has become even more important since the draft EA was published back in 2010. In May, 2012, it was reported that the water table in the Ann Arbor area, has risen substantially. As pointed out in the Ann Arbor Chronicle, "[t]he only hard data that the city has collected on the water table is at the municipal airport, and there the water table measures between 2-7 feet below the surface now, compared to 15 feet below the surface 50 years ago." Exhibit 30.[17] This is not an insubstantial problem. With the water table at the airport now being 2-7 feet below the ground surface instead of 15 feet, when the drinking water wells were first dug, the groundwater is even more vulnerable to contamination because there is much less soil for any surface pollution to filter through or attach to soil particles before it reaches the water table. This dramatic change in the water table may also alter ground water data from the past. That is, the rise in the water table may have altered the direction of groundwater flow, or there may now be some barrier blocking the traditional pathway for the water to flow, which would cause Ann Arbor's principal drinking water supply to be contaminated.

The Washtenaw County Water Resources Commissioner raised additional significant concerns that have yet to be addressed by either ARB or MDOT.

> 3. It is indicated that the preferred alternative does not impact the stream that is existing on the site. [Draft EA, p.4-18]. Using GIS measurements it appears that the stream is less than 1,000 linear feet from the existing runway. The runway extension would bring this infrastructure within 50 linear feet or less of the stream. In addition to this the grading limits shown in Appendix D-7 clearly extend into and beyond the location of the stream. Based on this information *it is not understood how it has been concluded that there are no impacts to the stream*.
>
> 4. It is indicated that the preferred alternative does not impact the floodplain for the stream that is existing on the site. It is indicated that proposed grading for the expansion would not occur within the designated floodplain boundary. [Draft EA, p.4-24]. Based on the floodplain boundary shown on FEMA Community-Panel Number: 260623 0010 C these statements are incorrect. Not only do the grading limits indicated for the preferred alternative extend into the floodplain boundary but the runway extension itself will extend into this floodplain boundary. Based on this information it is *not understood how it has been concluded that there are no impacts to the floodplain*.
>
> ….

[17] By contrast, the draft EA relies on data at least 15 years old. Since there is more current data, that should be used instead of outdated data. *See* Exhibit 26, p.4-20.

> 6. It is noted in the report that: "Implementation of appropriate best management practices (BMPs) would continue to control the rate of stormwater runoff and maintain water quality standards." [Draft EA, p.4-18]. It is unknown by this office as to what the control rate of stormwater is currently being implemented or whether this rate meets county standards. *The additional volume created by this increase in imperviousness is not spoken to at all by the report. The type or locations of the appropriate BMPs indicated are not identified*.

Exhibit 17, pp.1-2 (emphasis added). Petitioners have the same concerns about how water resources will be managed by ARB and MDOT should this Project move forward. These issues have not been sufficiently addressed by either ARB or MDOT in the draft EA or at any of the public hearings.

VI. REDRESS

By this Petition, and for the reasons stated above, Pittsfield Charter Township and the Committee for Preserving Community Quality, Inc. respectfully request that the Secretary of Transportation take the following actions with respect to Ann Arbor Municipal Airport, which is located solely in Pittsfield Charter Township:

1. Halt any further FAA action regarding MDOT and ARB's proposal to extend the primary runway at Ann Arbor Municipal Airport pending the resolution of this petition.

2. Vacate the current Airport Layout Plan as being improvidently approved by MDOT and reinstate the prior Airport Layout Plan.

3. Inform MDOT that federal funds may not be used for the extension of the primary runway at Ann Arbor Municipal Airport due to the fact that MDOT and ARB have failed to state a legitimate purpose and need for the extension.

4. Inform MDOT and ARB that should the primary runway be extended without the agreement or acquiescence of Pittsfield, it will be in violation of its federal grant assurances.

5. If the Secretary of Transportation fails to take the actions described in ¶¶ 3 and 4 above, Pittsfield Charter Township requests that he order that an Environmental Impact

Statement be conducted that assesses the impact the extension of the runway will have on the surrounding communities and that addresses the significant environmental impacts detailed in this Petition.

6. If the Secretary of Transportation declines to order that an Environmental Impact Statement be conducted, Petitioners request that the Secretary of Transportation direct MDOT to make federal block grant funds available to Pittsfield to conduct its own Environmental Assessment and/or Environmental Impact Statement. In addition, Petitioners request that the Secretary of Transportation inform MDOT and ARB that federal funds will not be available for the implementation of the extension of the runway until such time as Pittsfield completes its Environmental Impact Statement.

7. If the Secretary of Transportation declines to take any of the actions described in the above paragraphs, Petitioners request that the Secretary direct MDOT to conduct a written re-evaluation of the Project and publish a new draft Environmental Assessment, which would then be subject to public participation in the form of substantive public hearings and comments.

8. Inform MDOT and ARB that in order to use federal funds for any future airport actions that will affect the surrounding community in general and Pittsfield in particular, they must consult and receive approval from Pittsfield prior to commencing any such action.

VII. CONCLUSION

Federal law requires the Secretary of Transportation to give this petition prompt consideration. Additionally, under the Administrative Procedure Act "agency action" is defined to include "the whole or part of an agency rule, order, license, sanction, relief, or the equivalent denial there of *or failure to act.*" Therefore, Petitioners are requesting a substantive response to this petition within one hundred eighty (180) calendar days.[18] In the absence of an affirmative response, Petitioners will be compelled to consider litigation in order to achieve the agency actions requested.

Dated: January 28, 2013

BY LAWS OF THE
ANN ARBOR MUNICIPAL AIRPORT ADVISORY COMMITTEE

As adopted November 15, 1995
Revised and Approved at *the January* 25, *2006 Meeting*

WHEREAS, the Ann Arbor City Council has created the Airport Advisory Committee for the purpose of making recommendations to the Council regarding the construction and operation of the Airport, and

WHEREAS, the Committee size is established at seven (7) members, and

WHEREAS, the Committee finds it desirable to adopt By Laws so that it may more efficiently fulfill its obligations to the City and Council; and

WHEREAS, the Airport Advisory Committee is playing an increasingly important part in policy matters regarding the airport; and

WHEREAS, the need of diligence and continuity of effort has increased; and

WHEREAS, the members of the committee have expressed a desire to amend the By Laws which govern them;

THEREFORE, the Airport Advisory Committee has approved the following By Laws effective January 18, 1995, as amended April 17, 1996, May 15, 1996, July 17, 1996, June 18, 1997, April 15, 1998, November 18, 1998, June 20,2001, February 19, 2003 and January 25, 2006.

I

OFFICE

1. The principal office of the Committee shall be at the Ann Arbor Municipal Airport Administration Building.

2. The Committee may also have offices in such other places as the Committee may from time to time designate.

II

MEMBERS AND OFFICERS

1. The voting members of the Committee shall be seven (7) individuals duly designated by the Mayor and approved by City Council. Each new member shall serve for a term of three (3) years, and may serve no more than two (2) terms. A member whose term has expired may serve until a successor is appointed, or sixty days after the expiration of the term, whichever occurs first.

2. The Airport Manager shall be an ex-officio member without vote. Pittsfield and Lodi Townships may each name an ex-officio non-voting member to the committee.

3. Members are expected to attend all regularly scheduled and convened meetings of the Committee. Should a member miss two (2) meetings in succession or two (2) of four (4) meetings, the Chair may inquire of the absent member concerning their intention to continue serving on the Committee. Should a member miss three (3) meetings in succession or three (3) of five (5) meetings, the Chair may refer the name of the absent member to the Mayor of the City with the suggestion to dismiss the member and appoint another person to fill the unexpired term.

4. The officers of the Committee shall be a Chair, and Vice Chair. The Airport Manager shall serve as secretary.

5. The Committee at its November meeting shall choose the Chair and Vice Chair for one-year terms, effective at its next regularly scheduled meeting.

6. The Chair and Vice Chair shall hold office until their successors are chosen and qualify in their stead. If the office of Chair becomes vacant the Vice Chair shall succeed to that office for the unexpired term of that office. If the office of Vice Chair becomes vacant the Committee shall elect a successor from its membership at the next regular meeting, and such election shall be for the unexpired term of that office.

III

MEETINGS

1. Place. All meetings of the Committee shall be held at its offices at the Ann Arbor Municipal Airport Administration Building or at such other place as the Committee may from time to time designate.

2. Regular Meetings. Regular meetings of the Committee shall be held without notice on the third Wednesday of every other month (January, March, May, July, September, and November) at the offices of the Committee or such other time and place as may be designated in accordance with these By Laws.

3. Special Meetings. The Chair of the Committee may, when deemed by the Chair to be expedient, and shall, upon the request of at least one member of the Committee, call a special meeting of the Committee for the purpose of transacting any business designated in the call. The call for a special meeting may be issued to each member of the Committee no later than two (2) days prior to the date of such special meeting. At such special meeting, no business shall be considered other than as designated in the call, but if all of the voting members of the Committee are present at a special meeting any and all business may be transacted at such special meeting.

4. Quorum. At all meetings of the Committee, a majority of the appointed voting members of the Committee shall constitute a quorum for the purpose of transacting business. Ex-officio members of the Committee shall not be counted in determining a quorum.

5. Order of Business. At the regular meeting of the Committee the following shall be the order of business:

1. Roll Call
2. Approval of Agenda
3. Reading and approval of minutes of previous meeting
4. Audience participation
5. Reports of Airport Manager
6. Reports of Townships/FAA Tower Manager/Committees
7. Unfinished business
8. New Business
9. Items for Next Agenda
10. Notice of Next Scheduled Meeting
11. Adjournment

The order of business may be changed with the consent of a majority of members present.

6. Audience Participation. Audience participation in Committee meetings shall appear near the beginning of the agenda, for the purpose of addressing any item on the agenda. Speakers shall be limited to three minutes. However, the sole representative of a group may speak five minutes. Audience participation may also be permitted later, regarding items not on the agenda.

7. Rules of Parliamentary Procedure. The rules of parliamentary practice comprised in Roberts Rules of Order shall govern the Committee in all cases to which they are applicable, provided they are not in conflict with these By-Laws.

8 . Minutes of Proceedings. It shall be the responsibility of the secretary to prepare the minutes of the proceedings of each regular and special meeting of the Committee. At the option of the secretary, audio or video recordings may be utilized to assist in the production of written minutes.

IV

ANNUAL REPORT

The Committee shall present to the Ann Arbor City Council in the month of February of each year, a report on the activities of the Committee and the Airport for the past calendar year. The report may contain recommendations to the Council.

V

AMENDMENT TO THE BY LAWS

The By Laws of the Committee may be amended, added to, or repealed, or new By Laws may be adopted in lieu hereof by the affirmative vote of a majority of the Committee, provided that notice thereof shall be in the call of the meeting.

Exhibit 4

Council unanimously agreed with Councilmember Morris to amend Paragraph A of Section I (Annexation - General) of the policy agreement as follows:

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the ~~centerline~~ SOUTH LINE of Ellsworth Road from U.S. 23 to the west line of ~~Platt~~ STATE Road, ~~thence southerly to the Railroad right-of-way adjacent to the City Landfill, thence westerly along the landfill line extended to Stone School Road, thence northerly along the east line of Stone School Road to the south line of Ellsworth Road, thence westerly to the west line of State Street~~, thence northerly to the south line of I-94,...

The question being the Resolution with the amended Policy Agreement.

On a voice vote, Chair declared the motion carried unanimously.

The Resolution as adopted reads as follows:

R-280-7-78

RESOLUTION TO APPROVE CITY OF ANN ARBOR AND PITTSFIELD TOWNSHIP AGREEMENT

WHEREAS, the City of Ann Arbor officials and Pittsfield Township officials have spent many months negotiating an agreement of understanding; and,

WHEREAS, both governments agree to the principle of cooperation and not confrontation; and,

WHEREAS, the agreement is deemed in the best interests of the citizens of both units of government;

NOW, THEREFORE, BE IT RESOLVED that the following agreement of understanding be approved.

CITY OF ANN ARBOR–CHARTER TOWNSHIP OF PITTSFIELD POSITION PAPER ON PROMULGATION OF POLICIES

Promulgation of Policies

The CITY OF ANN ARBOR "The City", and the CHARTER TOWNSHIP OF PITTSFIELD, "The Township", by their respective governing bodies, for the purpose of furthering their common welfare, do hereby promulgate certain policies, and declare their intentions to abide the same in their exercise of governmental authority so far as practical and not in conflict with law.

I–ANNEXATION–GENERAL

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the south line of Ellsworth Road from U.S. 23 to the west line of State Road, thence

northerly to the south line of I-94, thence westerly to the western boundary of The Township, shall be designated as "The Territory" and shall be eventually annexed to the City in an orderly manner.

B. It shall be understood that this aforementioned line is the unofficial boundary line until such times it can be so officially designated.

C. Inasmuch as the Township and the City have an existing contract for sewer service for portions of the Township, the Township shall not make plans to provide municipal sewer and/or water service to any properties within said Territory, however the Township shall maintain all other legal authority and responsibility for Township lands and residents in the Territory until such time as they do become annexed to the City.

D. Notwithstanding previous policies, decisions and procedures, the City and Township hereby agree that individual properties in the designated area may be annexed to the City even where such annexation may create new islands. Neither the City nor the Township shall interpose in any judicial or other proceeding pertaining to the annexation of any portion of the said Territory an objection to such annexation by reason that the same would create an enclave of Township land within the City.

E. Neither the City nor the Township shall seek to require annexation to the City of any such enclave of Township land lying within the Territory, solely because of its constituting an enclave, whether now existing or hereafter created through the annexation of a portion of the Territory. Nevertheless, upon request to the City by the owner of a property within any said enclave for City water and/or sewer service to such property, the City may require such property to become annexed to the City as a condition of granting such service.

F. The Township agrees that rather than furthering litigation in the case of the Pittsfield Islands, it will agree to the Boundary Commission decision of 1973 (File No. 8322) if the individual review procedure as set forth in paragraph I-H is applied.

G. Through joint resolutions of the City and Township governing bodies any portion of the Territory within the designated area may be annexed to the City upon the petition therefor signed by the petitioners as provided by MCLA 117.9(8) in the case of such alternate method of annexation.

H. Upon annexation to the City of properties within said Territory the City "deferred charges" thereon, for benefits conferred by capital improvements made prior to the annexation shall be payable at the property owners option, either in full, or in not

less than six (6) equal annual installments, provided that the same shall be payable in up to twelve (12) equal annual installments in cases of a property being, and continuing to be, the homestead of an owner occupant who has special hardship problems or is otherwise adjudged in need of special consideration. Hardship and special considerations may be conferred upon the single owner occupant at time of annexation. A transition appeals committee shall be established for the purpose of determining such need. It shall be authorized to make recommendations to City Council for special consideration and shall be comprised of two (2) members appointed from the City and one (1) member appointed from the Township.

II–MUNICIPAL AIRPORT

A. The City agrees that the pending appeal of the decision of the Washtenaw Circuit Court in the suit of the Township vs. the City (Docket No. 77-12619) respecting the City's proceedings to annex Territories in and about the Municipal Airport and a portion of Eisenhower Boulevard shall be dismissed.

B. The Township agrees to cooperate with the City in the establishment of an Airport Land Use Plan which recognizes the compatibility of light industrial, warehousing, gravel mining and other uses on airport lands. The Township will review and comment on the plan before City adoption. It is further understood that any private construction on Airport lands will require approval under Township zoning and site plan requirements, as well as Township Building and Safety Department permit requirements. Plans for municipal construction on Airport lands must be submitted to the Township for review and comment.

C. The Township agrees to establish a land use plan for the environs of the Airport which recognizes only land uses which are compatible to airport operations from a safety and environmental point of view. The City will review and comment on the plan before adoption by the Township.

D. It is further agreed that gravel mining may take place only for use on City of Ann Arbor roads and public works projects and for use on Pittsfield Township roads, and public works projects. In addition, that a gravel processing plan, a restoration plan and a soil erosion plan be filed and reviewed by the Township.

E. Excepting as exempt by law, the Township shall assess for taxes the real and personal properties of and upon the airport lands.

F. The Township agrees to provide right-of-way for City sanitary sewage mains to the Airport to serve Airport properties uses only.

III–LANDFILL

A. The City desires to expand its Landfill operations to the west on property known as the Derck, Nielsen, and McCalla parcels.

B. The Township agrees to actively support and assist in acquisition negotiations such expansion on the conditions that:

1. A land use and restoration plan be developed for long range use of the landfill area.

2. That a reasonable strip of land immediately east of Stone School Road, as well as along Ellsworth Road, as well as along the northern edge of what is known as the Morgan properties is excluded for environmental purposes.

C. A Landfill Expansion Advisory Committee composed of four (4) persons appointed by the City and three (3) persons appointed by the Township shall be created to advise the City on environmental and operational plans.

D. The Township desires that it be given preferred customer consideration by the City in the use of the Landfill or offered an opportunity for proportionate investment equity if the Landfill is to be expanded in this location.

E. The Township shall not adopt any ordinance, rule or regulation which regulates or attempts to regulate the City's use of the landfill property so long as that property is used for disposal of refuse materials or for park purposes.

IV–SEWER/WATER SERVICEES

A. Upon acceptance and execution of this position paper, the City agrees to immediately approve the Township's request for sewer service limited to the Township Hall and the State Road frontage of a proposed commercial development at Ellsworth and State Roads in accordance with procedures established in Paragraph I-A of the Ann Arbor Pittsfield Sewer Service Agreement dated September 30, 1975. It is understood State Department of Natural Resources approval will be sought eagerly by the City.

B. The sewer service will be provided at 103% of City rates in accordance with the aforementioned agreement.

C. The City will agree to consider additional requests for service prior to the completion of the new "area wide treatment plant" on a case by case basis.

COMMUNICATIONS FROM THE MAYOR

Mayor Louis D. Belcher informed Councilmembers that he will be communicating with Mr. Robert Lillie, Pittsfield Township Supervisor, to advise him of the changes made tonight in the Pittsfield Township Agreement.

* *

Mayor Belcher alerted Council that there are several major Planning matters comming up for consideration, such as the eighty acres of land to be developed in the Briarwood area and a proposal for downtown housing.

* *

Mayor Belcher recommended the appointment of Hugh M. Wanty, 2061 Pauline Boulevard, to the Housing Board of Appeals to replace James J. O'Kane for an indefinite term.

Moved by Councilmember Trowbridge that Council concur in the recommendation of the Mayor.

On roll call the vote was as follows: Yeas, Councilmembers Latta, Greenberg, Morris, Senunas, Sheldon, Trowbridge, Cmejrek, Mayor Belcher, 8

Nays, 0

Councilmember Bell was absent from the Council Chamber at the time the vote was taken.

Chair declared the motion carried.

* *

Mayor Belcher recommended the appointment of Roberta Lea Shrope, 321 South Revena Boulevard, to the Planning Commission, effective July 1, 1978 for a three year term ending June 30, 1981.

Moved by Councilmember Cmejrek that Council concur in the recommendation of the Mayor.

On roll call the vote was as follows: Yeas, Councilmembers Senunas, Sheldon, Trowbridge, Cmejrek, Bell, Mayor Belcher, 6

Nays, Councilmembers Latta, Greenberg, Morris, 3

Chair declared the motion carried.

* *

Mayor Belcher laid the nomination on the table of Charles T. Wagner, 3425 Brentwood Court, to the Planning Commission to be confirmed at the next session of Council.

COMMUNICATIONS FROM COUNCIL COMMITTEES

None.

Exhibit 5

AGREEMENT SUPPLEMENTING 1979 POLICY STATEMENT RELATIVE TO AIRPORT LAYOUT PLANS, AERONAUTICAL FACILITIES AND NON-AERONAUTICAL FACILITIES AT THE ANN ARBOR AIRPORT

This agreement ("Agreement") is between the City of Ann Arbor ("Ann Arbor"), a Michigan Municipal Corporation and Pittsfield Charter Township ("Pittsfield"), a Michigan Municipal Corporation.

RECITALS:

Ann Arbor owns and operates the Ann Arbor Airport ("Airport"), which is located in Pittsfield Charter Township.

In 1979 Pittsfield and Ann Arbor entered into an agreement entitled "Policy Statement," a portion of which has addressed certain aspects of the operation of the Ann Arbor Airport.

This Agreement is not intended to replace the Policy Statement. However, in the event of any conflict with the Policy Statement, this agreement shall apply.

Under the Michigan Aeronautics Code, MCL 259.1 et seq., Ann Arbor has jurisdictional control for the management, governance and use of the Airport, including application of its police powers, rules, regulations and ordinances, and including the zoning and planning of aeronautical facilities on the Airport property.

The City of Ann Arbor has adopted its construction code, including the building code, electrical code and mechanical code components thereof, in accordance with the Stille-DeRossett-Hale Single State Construction Code Act (MCL 125.1501 et seq.) ("construction code"). The City and the Township do not agree as to the authority granted to the City by the Michigan Aeronautics Code to extend and enforce its construction code at the Airport relative to aeronautical facilities. However, without deciding the extent of the City's authority under the Michigan Aeronautics Code, the City and the Township agree that to the extent it may be necessary, this agreement is an agreement between two public agencies that constitutes an interlocal agreement for purposes of Sections 4 and 5 of the Urban Cooperation Act (MCL 124.504 and 124.505) and Subsection 8b(2) of the Stille-DeRossett-Hale Single State Construction Code Act (MCL 125.1508b(2)) by which the City and the Township agree that the City shall extend and enforce its construction code to all aeronautical facilities constructed on Airport property, including issuing permits, inspections and enforcement of violations.

The Airport is serviced in whole by Pittsfield sanitary sewer service and is serviced in part by Pittsfield water service.

Unless and until Ann Arbor or the Airport qualifies as an authorized public agency for the Airport under Section 9110 of Part 91, Soil Erosion and Sedimentation Control, of

the Natural Resources and Environmental Protection Act, MCL 324.9110, Pittsfield has jurisdiction over the Airport for soil erosion and sedimentation control.

Wherefore, the parties agree as follows:

1. "Aeronautical facilities" means Airport buildings, landing fields and other facilities that are used for and serve aeronautical or aeronautically related operations and purposes. Aeronautical facilities include both facilities constructed by Ann Arbor and facilities that are privately constructed.

2. "Non-aeronautical facilities" means facilities whose use is unrelated to aeronautical operations or purposes.

3. A modification of the Airport Layout Plan is a land use plan as used in Section II.B. of the Policy Statement.

4. If a modification of the Airport Layout Plan is proposed, Ann Arbor will give notice to Pittsfield's Building Official or such other person as Pittsfield designates in writing, of the intent to modify the Airport layout plan at least 30 days before authorizing a professional services agreement for the modification. At least 30 days before submitting a modification of the Airport Layout Plan for approval by the Michigan Aeronautics Commission or the Federal Aviation Administration, Ann Arbor will provide Pittsfield's Building Official with copies of the documents to be submitted to those bodies. After approval of a modified Airport Layout Plan by the Michigan Aeronautics Commission or the Federal Aviation Administration, Ann Arbor will provide Pittsfield's Building Official with a copy of the proposed modification at least 30 days before the Ann Arbor City Council meeting at which it is to be submitted for approval.

5. Annually Ann Arbor will provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with a copy of the five year Airport Improvement Plan for the Airport.

6. If Ann Arbor applies for grant funds for new or expanded facilities shown or listed on the Airport Layout Plan or Airport Improvement Plan it will notify Pittsfield's Building Official, or such other person as Pittsfield designates in writing, of the application.

7. Aeronautical facilities being constructed at the Ann Arbor Airport are not required to go through the Pittsfield site plan review and approval process. However, when civil construction drawings for a project have been completed, but prior to bid for construction of the facilities, Ann Arbor will submit copies of the civil construction drawings to Pittsfield's Building Official, or such other person as Pittsfield designates in writing, for review and comment. The plans submitted to Pittsfield shall consist of four (4) sets of full sized drawings and a description of

the type of project, the general scope and the time frame. All proposed utilities associated with civil construction drawings for a project shall meet all current Township Land Development Standards.

8. Typical administrative fees will not be charged for the review of the plans submitted pursuant to paragraph 7, but the City will be responsible for establishing an Airport Plan (AP) escrow account for costs, which Pittsfield agrees shall be limited to its actual costs for plan review and comment.

9. Pittsfield will provide a written evaluation of the plans specified in paragraph 7 based on the Pittsfield Zoning Ordinance and Land Development Standards to Ann Arbor's Fleet & Facilities Manager, or such other person as Ann Arbor designates in writing, within two (2) weeks of the submittal in order to permit Ann Arbor staff to consider its comments.

10. Ann Arbor will consider and endeavor to incorporate reasonable recommendations provided by Pittsfield.

11. Ann Arbor will obtain soil erosion and sedimentation control permits for the Airport from Pittsfield until such time as Ann Arbor or the Airport qualifies as an authorized public agency for the Airport under Section 9110 of Part 91, Soil Erosion and Sedimentation Control, of the Natural Resources and Environmental Protection Act, MCL 324.9110.

12. Ann Arbor will obtain Pittsfield utility permits as required by Pittsfield ordinance for connections to Pittsfield sanitary sewer or water lines.

13. Ann Arbor shall extend and enforce its construction code, including the building code, electrical code and mechanical code components thereof, to all aeronautical facilities constructed on Airport property and provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with copies of all construction permit documents including the application, the permit, inspection reports and any certificate of occupancy within thirty days of being issued or received.

14. Non-aeronautical facilities at the Airport will be required to comply with Pittsfield planning and zoning requirements and the Pittsfield construction code ordinance.

15. Nothing contained in this agreement shall be construed as limiting Pittsfield's authority to enforce the State Construction Code regarding any violations of that code for non-aeronautical facilities.

16. Nothing contained in this agreement shall exempt aeronautical facilities from being in compliance with the State Construction Code unless said facilities are under the jurisdiction of the Federal Aviation Administration.

17. Ann Arbor shall extend and enforce its fire prevention code to all aeronautical facilities located on Airport property and provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with copies of all fire inspection documents including fire alarm and detection systems and fire extinguishing system certification and test reports, and all required operational permits within thirty days of being issued or received.

18. This agreement shall be approved by the concurrent resolutions of the Ann Arbor City Council and Pittsfield Charter Township Board of Trustees.

19. This agreement shall take effect October 1, 2009 or after a copy has been filed with both the Washtenaw County Clerk and the Michigan Secretary of State, whichever is later.

20. This agreement shall have a term of 5 years beginning on October 1, 2009. It shall automatically renew for successive 5 year periods unless either party provides the other with written notice of non-renewal at least 60 days before the end of a term.

Council unanimously agreed with Councilmember Morris to amend Paragraph A of Section I (Annexation - General) of the policy agreement as follows:

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the ~~centerline~~ SOUTH LINE of Ellsworth Road from U.S. 23 to the west line of ~~Platt~~ STATE Road, ~~thence southerly to the Railroad right-of-way adjacent to the City Landfill; thence westerly along the landfill line extended to Stone School Road, thence northerly along the east line of Stone School Road to the south line of Ellsworth Road; thence westerly to the west line of State Street~~, thence northerly to the south line of I-94,...

The question being the Resolution with the amended Policy Agreement.

On a voice vote, Chair declared the motion carried unanimously.

The Resolution as adopted reads as follows:

R-280-7-78

RESOLUTION TO APPROVE CITY OF ANN ARBOR AND PITTSFIELD TOWNSHIP AGREEMENT

WHEREAS, the City of Ann Arbor officials and Pittsfield Township officials have spent many months negotiating an agreement of understanding; and,

WHEREAS, both governments agree to the principle of cooperation and not confrontation; and,

WHEREAS, the agreement is deemed in the best interests of the citizens of both units of government;

NOW, THEREFORE, BE IT RESOLVED that the following agreement of understanding be approved.

CITY OF ANN ARBOR–CHARTER TOWNSHIP OF PITTSFIELD POSITION PAPER ON PROMULGATION OF POLICIES

Promulgation of Policies

The CITY OF ANN ARBOR "The City", and the CHARTER TOWNSHIP OF PITTSFIELD, "The Township", by their respective governing bodies, for the purpose of furthering their common welfare, do hereby promulgate certain policies, and declare their intentions to abide the same in their exercise of governmental authority so far as practical and not in conflict with law.

I–ANNEXATION–GENERAL

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the south line of Ellsworth Road from U.S. 23 to the west line of State Road, thence

northerly to the south line of I-94, thence westerly to the western boundary of The Township, shall be designated as "The Territory" and shall be eventually annexed to the City in an orderly manner.

B. It shall be understood that this aforementioned line is the unofficial boundary line until such times it can be so officially designated.

C. Inasmuch as the Township and the City have an existing contract for sewer service for portions of the Township, the Township shall not make plans to provide municipal sewer and/or water service to any properties within said Territory, however the Township shall maintain all other legal authority and responsibility for Township lands and residents in the Territory until such time as they do become annexed to the City.

D. Notwithstanding previous policies, decisions and procedures, the City and Township hereby agree that individual properties in the designated area may be annexed to the City even where such annexation may create new islands. Neither the City nor the Township shall interpose in any judicial or other proceeding pertaining to the annexation of any portion of the said Territory an objection to such annexation by reason that the same would create an enclave of Township land within the City.

E. Neither the City nor the Township shall seek to require annexation to the City of any such enclave of Township land lying within the Territory, solely because of its constituting an enclave, whether now existing or hereafter created through the annexation of a portion of the Territory. Nevertheless, upon request to the City by the owner of a property within any said enclave for City water and/or sewer service to such property, the City may require such property to become annexed to the City as a condition of granting such service.

F. The Township agrees that rather than furthering litigation in the case of the Pittsfield Islands, it will agree to the Boundary Commission decision of 1973 (File No. 8322) if the individual review procedure as set forth in paragraph I-H is applied.

G. Through joint resolutions of the City and Township governing bodies any portion of the Territory within the designated area may be annexed to the City upon the petition therefor signed by the petitioners as provided by MCLA 117.9(8) in the case of such alternate method of annexation.

H. Upon annexation to the City of properties within said Territory the City "deferred charges" thereon, for benefits conferred by capital improvements made prior to the annexation shall be payable at the property owners option, either in full, or in not

less than six (6) equal annual installments, provided that the same shall be payable in up to twelve (12) equal annual installments in cases of a property being, and continuing to be, the homestead of an owner occupant who has special hardship problems or is otherwise adjudged in need of special consideration. Hardship and special considerations may be conferred upon the single owner occupant at time of annexation. A transition appeals committee shall be established for the purpose of determining such need. It shall be authorized to make recommendations to City Council for special consideration and shall be comprised of two (2) members appointed from the City and one (1) member appointed from the Township.

II–MUNICIPAL AIRPORT

A. The City agrees that the pending appeal of the decision of the Washtenaw Circuit Court in the suit of the Township vs. the City (Docket No. 77-12619) respecting the City's proceedings to annex Territories in and about the Municipal Airport and a portion of Eisenhower Boulevard shall be dismissed.

B. The Township agrees to cooperate with the City in the establishment of an Airport Land Use Plan which recognizes the compatibility of light industrial, warehousing, gravel mining and other uses on airport lands. The Township will review and comment on the plan before City adoption. It is further understood that any private construction on Airport lands will require approval under Township zoning and site plan requirements, as well as Township Building and Safety Department permit requirements. Plans for municipal construction on Airport lands must be submitted to the Township for review and comment.

C. The Township agrees to establish a land use plan for the environs of the Airport which recognizes only land uses which are compatible to airport operations from a safety and environmental point of view. The City will review and comment on the plan before adoption by the Township.

D. It is further agreed that gravel mining may take place only for use on City of Ann Arbor roads and public works projects and for use on Pittsfield Township roads, and public works projects. In addition, that a gravel processing plan, a restoration plan and a soil erosion plan be filed and reviewed by the Township.

E. Excepting as exempt by law, the Township shall assess for taxes the real and personal properties of and upon the airport lands.

F. The Township agrees to provide right-of-way for City sanitary sewage mains to the Airport to serve Airport properties uses only.

III–LANDFILL

A. The City desires to expand its Landfill operations to the west on property known as the Derck, Nielsen, and McCalla parcels.

B. The Township agrees to actively support and assist in acquisition negotiations such expansion on the conditions that:

1. A land use and restoration plan be developed for long range use of the landfill area.

2. That a reasonable strip of land immediately east of Stone School Road, as well as along Ellsworth Road, as well as along the northern edge of what is known as the Morgan properties is excluded for environmental purposes.

C. A Landfill Expansion Advisory Committee composed of four (4) persons appointed by the City and three (3) persons appointed by the Township shall be created to advise the City on environmental and operational plans.

D. The Township desires that it be given preferred customer consideration by the City in the use of the Landfill or offered an opportunity for proportionate investment equity if the Landfill is to be expanded in this location.

E. The Township shall not adopt any ordinance, rule or regulation which regulates or attempts to regulate the City's use of the landfill property so long as that property is used for disposal of refuse materials or for park purposes.

IV–SEWER/WATER SERVICEES

A. Upon acceptance and execution of this position paper, the City agrees to immediately approve the Township's request for sewer service limited to the Township Hall and the State Road frontage of a proposed commercial development at Ellsworth and State Roads in accordance with procedures established in Paragraph I-A of the Ann Arbor Pittsfield Sewer Service Agreement dated September 30, 1975. It is understood State Department of Natural Resources approval will be sought eagerly by the City.

B. The sewer service will be provided at 103% of City rates in accordance with the aforementioned agreement.

C. The City will agree to consider additional requests for service prior to the completion of the new "area wide treatment plant" on a case by case basis.

R-31-1-07 APPROVED

RESOLUTION TO APPROVE THE URS CORPORATION AIRPORT LAYOUT PLAN UPDATE FOR THE ANN ARBOR MUNICIPAL AIRPORT, WHICH ILLUSTRATES EXISTING AND PROPOSED FACILITIES TO MEET THE FUTURE DEMANDS OF AIRPORT TENANTS AND USERS

Whereas, An approved Airport Layout Plan (ALP) is required by the FAA and the Michigan Department of Transportation (MDOT)-Bureau of Aeronautics for the Ann Arbor Municipal Airport to participate in the federal and state airport improvement program;

Whereas, The airport's ALP is no longer current and does not depict all airport facilities as required by the FAA and MDOT-Bureau of Aeronautics;

Whereas, The MDOT-Bureau of Aeronautics and FAA, funded the ALP Update at a cost split of 90% Federal, 5% State, and 5% City and URS Corporation a Michigan Planning and Consulting firm was selected to develop the plan;

Whereas, The recommended ALP document depicts existing and future airport facilities and was completed using FAA and MDOT design and planning standards, which included the requirement for participation by users, tenants and the general public; and

Whereas, On July 19, 2006, the Airport Advisory Committee voted unanimously to recommend City Council approval of the ALP Update for the Ann Arbor Municipal Airport;

RESOLVED, That Council approve the ALP Update for the Ann Arbor Municipal Airport;

RESOLVED, That the Mayor and City's Airport Manager be hereby authorized and directed to execute said ALP Document after approval as to form by the City Attorney and approval as to substance by the City Administrator; and

RESOLVED, That the City Administrator be authorized to take the necessary administrative actions to implement this resolution.

Councilmember Higgins moved, seconded by Councilmember Teall, that the

- Staff to bring back a separate proposal regarding extending the runway within the next 60 days and that notification of the proposal be sent out to citizens in the surrounding area.

On a voice vote, the Mayor declared the motion carried.

R-32-1-07 APPROVED

RESOLUTION ACCEPTING UTILITY EASEMENT FROM PLYMOUTH GREEN CROSSINGS, L.L.C.

Whereas, Plymouth Green Crossings, L.L.C., a Michigan limited liability company, is the fee simple owner of property located in the City of Ann Arbor, Washtenaw County, Michigan as described in the Washtenaw County Records at Liber 4539, Page 688, recorded February 21, 2006;

Whereas, The First Amended and Restated Operating Agreement of Plymouth Green Crossings, L.L.C., dated August 30, 2006, authorizes the delivery of a perpetual easement to the City for public utilities; and

Whereas, Plymouth Green Crossings, L.L.C., has delivered an easement to the City for the construction and maintenance of municipally operated public services comprising the public utilities system to run with the land and burden the respective property perpetually, being more particularly described as follows:

Description of Variable Width Water Main:

Commencing at the center of Section 14, Town 2 S, Range 6 E, City of Ann Arbor, Washtenaw County, Michigan; thence S 00°05'25" W 667.92 feet along the N and S 1/4 line of said Section 14; thence N 89°54'35" W 40.00 feet to a point on the Westerly right-of-way line of Green Road; thence along the said right-of-way line in the following courses: Southerly 46.90 feet along the arc of a 490.00 foot radius circular curve to the left through a central angle of 05°29'00" having a chord which bears S 02°39'05" E 46.88 feet, S 05°23'35" E 353.86 feet, Southerly 271.22 feet along the arc of a 630.00 foot radius circular curve to the right through a central angle of 24°40'00" having a chord which bears S 06°56'25" W 269.13 feet and S 19°16'25" W 71.37 feet; thence N 90°00'00" W 213.38 feet to the POINT OF BEGINNING;

thence S 56°41'39" W 101.15 feet;
thence N 89°54'35" W 139.18 feet;
thence S 45°05'25" W 24.77 feet;
thence S 00°05'25" W 34.72 feet;

Subject: Ann Arbor Municipal Airport Layout Plan (revision)

Dear Mr. Pierce:

The Ann Arbor City Council, at their January 22, 2007 meeting, approved an action directing staff to revise the Airport Layout Plan (ALP) to reflect a 4,300 feet runway and return that Plan to Council for consideration within 60 days. Council has been informed that the process for revising the ALP is underway but cannot be completed within 60 days.

Please accept this letter as our request to revise the ALP to show the runway improvement. My understanding is that this process begins with resubmitted drawings and an airspace review by the FAA. The Airport's consultant, URS Corporation, has completed the revisions to the drawings showing the 800 feet runway improvement and will be submitting those to you under separate cover. If you have any questions or need additional information, please contact me at (734) 972-9112.

Sincerely,

Matthew J. Kulhanek

Subject: Ann Arbor Municipal Airport Layout Plan

Dear Mr. Pierce:

Enclosed please find one complete set of drawings and three signed cover sheets for the approved Airport Layout Plan of the Ann Arbor Municipal Airport. The documents were approved by the City Council at their meeting on January 22, 2007. If you have any questions or need additional information, please contact me at (734) 972-9112.

Sincerely,

Matthew J. Kulhanek

Exhibit 8

PITTSFIELD CHARTER TOWNSHIP
WASHTENAW COUNTY, MICHIGAN
RES #09-23
RESOLUTION OPPOSING PROPOSED EXPANSION OF THE ANN ARBOR MUNICIPAL AIRPORT RUNWAY

MARCH 24, 2009

Minutes of a Regular Meeting of the Township Board of Pittsfield Charter Township, Washtenaw County, Michigan, held at the Township Administration Building located at 6201 W. Michigan Avenue, in said Township, on the 24th day of March, at 6:30 p.m.

Members Present: Grewal, Israel, Scribner, Ferguson, Hunt, Krone, Yi.
Members Absent: None.

The following preamble and resolution were offered by Member Scribner and supported by Member Ferguson.

WHEREAS, the Ann Arbor airport is under the jurisdiction of the City of Ann Arbor and operated by an independent Authority and the land is located within Pittsfield Charter Township immediately adjacent to a residential area; and

WHEREAS, the existing width and length has not posed any substantial safety concerns in the past with only five incidents of landing mishaps out of a total of 600,000 landings in the past eight years; and

WHEREAS, the proposed changes and expansion would shift the runway dangerously close to a busy township roadway (Lohr Road) and closer to dense residential subdivisions; and

WHEREAS, such a runway expansion will significantly increase air traffic volumes and noise pollution experienced by residential subdivisions in the vicinity of the Ann Arbor airport, thereby resulting in a decline of residential home property values; and

WHEREAS, the City of Ann Arbor has not fully demonstrated the economic and safety justifications for undertaking the proposed runway expansion; and

WHEREAS, the City of Ann Arbor appears to have not taken into consideration the negative safety implications such a runway expansion may impose on the surrounding residential subdivisions by expanding a runway closer to residential subdivisions

NOW THEREFORE BE IT RESOLVED, the Pittsfield Charter Township Board of Trustees urges the City of Ann Arbor to reconsider the merits of expanding the Ann Arbor Airport runway in light of the negative implications such an expansion would impose on the residents of Pittsfield Charter Township.

AYES: Grewal, Israel, Scribner, Ferguson, Hunt, Krone, Yi.
NAYS: None.
ABSENT: None.
ABSTAIN: None.

RESOLUTION DECLARED ADOPTED.

Alan Israel

Alan Israel, Clerk
Pittsfield Charter Township

DATED: March 24, 2009.

CERTIFICATE

I, Alan Israel hereby certify that the foregoing is a true and complete copy of a resolution adopted by the Township Board of Pittsfield Charter Township, County of Washtenaw, State of Michigan, at a Regular Meeting held on March 24, 2009, and that said meeting was conducted and public notice of said meeting was given pursuant to and in full compliance with the Open Meetings Act, being Act 267, Public Acts of Michigan, 1976, and that the minutes of said meeting were kept and will be or have been made available as required by said Act.

Alan Israel, Clerk
Pittsfield Charter Township

DATED: March 24, 2009.

Exhibit 9

LODI TOWNSHIP
WASHTENAW COUNTY, MICHIGAN
RESOLUTION # 2009-009
A RESOLUTION OPPOSING PROPOSED RUNWAY EXPANSION OF THE ANN ARBOR MUNICIPAL AIRPORT

WHEREAS, the Ann Arbor airport is under the jurisdiction of the City of Ann Arbor and operated by an independent Authority and the land is located within Pittsfield Charter Township immediately adjacent to residential areas, including Lodi Township;

WHEREAS, the existing width and length of Runway 6-24 has not be posed any substantial safety concerns in the past with only five incidents of landing mishaps out of a total of 600,000 landings in the past eight years; and

WHEREAS, the proposed changes and expansion would shift the runway so that it ends a mere 700 yards from a busy roadway (Lohr Road) and closer to dense residential subdivisions; and

WHEREAS, such a runway will significantly accommodate larger and heavier aircraft, increase air traffic volumes, and increase noise pollution experienced by residential subdivisions in the vicinity of the Ann Arbor airport, thereby resulting in a decline in residential home property values; and

WHEREAS, the City of Ann Arbor has not fully demonstrated the economic and safety justifications for undertaking the proposed runway expansion; and

WHEREAS, the City of Ann Arbor appears to have not taken into consideration the negative safety implications such a runway expansion may impose on the surrounding residential subdivisions by expanding a runway closer to residential subdivisions;

NOW, THEREFORE BE IT RESOLVED, the Lodi Township Board of Trustees urge the City of Ann Arbor to reconsider the merits of expanding the Ann Arbor Airport runway in light of the negative implications such an expansion would impose on the residents of Lodi Township.

ROLL CALL VOTE:
Ayes: Masters, Staebler, Lindemann, Canham, Foley, and Godek.
Nays: Rentschler.
Absent: None.
Abstain: None.

RESOLUTION DECLARED ADOPTED

____
Elaine Masters, Clerk, Lodi Township
DATED: May 12, 2009

Exhibit 10

car owners relative to identification marks on railroad equipment. FRA, railroads, and the public refer to the stenciling to identify freight cars.

Annual Estimated Burden Hours: 18,750 hours.

Title: Rear-End Marking Devices.

OMB Control Number: 2130–0523.

Type of Request: Extension of a currently approved collection.

Affected Public: Railroads.

Abstract: The collection of information is set forth under 49 CFR Part 221 which requires railroads to furnish a detailed description of the type of marking device to be used for the trailing end of rear cars in order to ensure rear cars meet minimum standards for visibility and display. Railroads are required to furnish a certification that the device has been tested in accordance with current "Guidelines For Testing of Rear End Marking Devices." Additionally, railroads are required to furnish detailed test records which include the testing organizations, description of tests, number of samples tested, and the test results in order to demonstrate compliance with the performance standard.

Annual Estimated Burden Hours: 89 hours.

Title: Locomotive Certification (Noise Compliance Regulations).

OMB Control Number: 2130–0527.

Type of Request: Extension of a currently approved collection.

Affected Public: Railroads.

Abstract: Part 210 of title 49 of the United States Code of Federal Regulations (CFR) pertains to FRA's noise enforcement procedures which encompass rail yard noise source standards published by the Environmental Protection Agency (EPA). EPA has the authority to set these standards under the Noise Control Act of 1972. The information collected by FRA under Part 210 is necessary to ensure compliance with EPA noise standards for new locomotives.

Annual Estimated Burden Hours: 2,767 hours.

ADDRESSES: Send comments regarding these information collections to the Office of Information and Regulatory Affairs, Office of Management and Budget, 725 Seventeenth Street, NW., Washington, DC, 20503, *Attention:* FRA Desk Officer. Alternatively, comments may be sent via e-mail to the Office of Information and Regulatory Affairs (OIRA), Office of Management and Budget, at the following address: *oira_submissions@omb.eop.gov.*

Comments are invited on the following: Whether the proposed collections of information are necessary for the proper performance of the functions of the Department, including whether the information will have practical utility; the accuracy of the Department's estimates of the burden of the proposed information collections; ways to enhance the quality, utility, and clarity of the information to be collected; and ways to minimize the burden of the collections of information on respondents, including the use of automated collection techniques or other forms of information technology.

A comment to OMB is best assured of having its full effect if OMB receives it within 30 days of publication of this notice in the **Federal Register**.

Authority: 44 U.S.C. 3501–3520.

Issued in Washington, DC, on June 11, 2009.

Donna M. Alwine,

Acting Director, Office of Financial Management, Federal Railroad Administration.

DEPARTMENT OF TRANSPORTATION

Federal Aviation Administration

FAA Notice of Intent to Prepare an Environmental Assessment; Ann Arbor Municipal Airport, Ann Arbor, MI

AGENCY: The Federal Aviation Administration, Department of Transportation.

ACTION: Notice of Intent to prepare an Environmental Assessment (EA) and conduct Citizen Advisory Meetings.

SUMMARY: The FAA has delegated selected responsibilities for compliance with the National Environmental Policy Act to the MDOT as part of the State Block Grant Program authorized under Title 49 U.S.C., Section 47128. This notice is to advise the public pursuant to the National Environmental Policy Act of 1969, as amended, (NEPA) 42 U.S.C. 4332(2)(c) that MDOT intends to prepare an EA for the proposed extension of runway 6/24 at the Ann Arbor Municipal Airport. While not required for an EA, the FAA and MDOT are issuing this Notice of Intent to facilitate public involvement. This EA will assess the potential environmental impacts resulting from the proposed extension of runway 6/24 from 3,500 feet to 4,300 feet. All reasonable alternatives will be considered including a no action alternative.

FOR FURTHER INFORMATION CONTACT: Ms. Molly Lamrouex, Environmental Specialist, Bureau of Aeronautics and Freight Services, MDOT, 2700 Port Lansing Road, Lansing, Michigan (517) 335–9866.

SUPPLEMENTARY INFORMATION: The EA will include analysis which will be used to evaluate the potential environmental impacts in the study area. During scoping, and upon publication of a draft EA and a final EA, MDOT will be coordinating with federal, state and local agencies, as well as the public, to obtain comments and suggestions regarding the EA for the proposed project. The EA will assess potential impacts and reasonable alternatives including a no action alternative pursuant to NEPA; FAA Order 1050.1E, Policies and Procedures for Considering Environmental Impacts; FAA Order 5050.4B, National Environmental Policy Act (NEPA) Implementing Instructions for Airport Actions; and the President's Council on Environmental Quality (CEQ) Regulations implementing the provisions of NEPA, and other appropriate Agency guidance.

Public Input Process: During development of the draft EA, a series of meetings to provide for public input will be held to identify potentially significant issues or impacts related to the proposed action that should be analyzed in the EA. For more information regarding the meetings for public input contact Molly Lamrouex, MDOT Bureau of Aeronautics and Freight Services, (517) 335–9866.

Issued in Romulus, Michigan, June 4, 2009.

Matthew J. Thys,

Manager, Detroit Airports District Office, Great Lakes Region.

See attached list.	

DISCUSSION

The first Citizens Advisory Committee (CAC) meeting was held to discuss: 1) the purpose and mission of the CAC, 2) study history and purpose and need, 3) airport improvements, 4) the Environmental Assessment process, 5) study status and next steps, and 6) questions and answers.

Purpose and Mission of CAC

The CAC was established to provide a means to communicate with those interested in the activities occurring at the Ann Arbor Airport. The people that participate in the CAC are intended to represent a wide variety of potentially interested stakeholder groups. The CAC does not have formal decision-making powers and is acting only in an advisory role. The CAC will help guide the study process and will help communicate the results of the study back to their respective stakeholder groups.

If there are people that are interested in the CAC activities, they are encouraged to contact members of the CAC to express their concerns or questions. These individuals can also submit comments independently to the City and/or JJR. These individuals are encouraged to attend the public hearing in the fall and to provide comments during the public comment period.

Study History and Purpose and Need

In 2007, an Airport Layout Plan (ALP) was approved that depicted a bump out in State Road to provide adequate distance between the end of Runway 6/24 and State Road. In 2008, after discussing the State Road Corridor Study recommendations with local road commission and township officials, a revised ALP was approved that eliminated the bump out of State Road and resolved the distance conflict by proposing a shift of Runway 6/24. The new ALP includes a 150 foot shift of the primary runway, a 950 foot extension (a net increase of 800 feet), and an adjustment of the taxiway and holding bay. The 2008 ALP was approved by MDOT and FAA. It was then approved by City Council in September 2008.

The improvements at the Airport are being proposed to:

1. Provide the recommended runway length to accommodate the B-II category Critical Aircraft that are presently using the airport.
2. Minimize the FAA tower line of sight issues.

3. Address the need for a future 34:1 approach slope on Runway 24.
4. Minimize the occurrence of runway overrun incidents.

Airport Improvements

The proposed improvements at the airport include:

1. Shifting Runway 6/24 150 feet to the southwest.
2. Extending Runway 6/24 by 800 feet, from 3,500 feet to 4,300 feet in total overall length.
3. Moving the holding bay so it is parallel with Runway 6/24 instead of being perpendicular to the runway.
4. The parallel taxiway will be extended to meet the new Runway 6/24 end.

All existing runway and taxiway widths will be maintained. The offset between the runway and taxiway will also be maintained. Any changes to surface drainage will be retained within Airport property. Other alternatives were evaluated that included rotation of the runway, however, none showed merit.

There will be no changes to the fencing at the Airport.

Environmental Assessment Process

The preparation of an Environmental Assessment (EA) is governed by the National Environmental Policy Act (NEPA), 1969, under guidance from the FAA. An EA is intended to be a concise public document that analyzes the environmental impacts of a proposed action. An EA will document, 1) the need for the proposed improvements, 2) alternatives considered, 3) proposed improvements, 4) potential environmental impacts, 5) mitigation measures, and 6) agency coordination and public participation

Following preparation of the EA, the document is then distributed to the public and is available for review and comment during the public comment period. During the 30 day comment period, the document is distributed to resource and regulatory agencies for review and it is available to the public for review. Copies of the document will be made available at public locations: libraries, airport, local municipalities, etc. During those 30 days, comments will be accepted from those interested in the proposed project. At the end of the 30 days, a public hearing will be held.

The EA is a tool to determine whether to prepare an Environmental Impact Statement (EIS) or a Finding of No Significant Impact (FONSI). If the EA concludes that the proposed improvements will not have potential “significant” impacts, a FONSI is prepared. A FONSI is a public document that explains the federal agency’s (FAA) conclusion as to why a proposed action would not have a significant effect on the natural and human environment. The FONSI will also outline proposed measures to mitigate impacts as agreed to in the EA. The FONSI will be jointly signed by both MDOT and FAA.

If it is determined that the project would have significant impact, additional studies may be needed and/or an EIS may be prepared.

Study Status and Next Steps
The overall study will be completed by January 2010. Currently, the study team is still completing the environmental investigations. This will be followed by the preparation of a draft EA. Following a review of the EA by MDOT and the City, the EA will be distributed and the 30 day public comment period will begin. A public hearing will be held at the end of the comment period, which is anticipated to occur in late fall. Following the public hearing, the document will receive State and Federal clearance, and, if appropriate, a FONSI will be prepared. The final EA will be distributed by MDOT.
There will be two more CAC meetings. The second CAC meeting will likely be in July and the third meeting will in October.

Questions and Answers
Throughout the meeting, CAC members asked questions regarding the information presented. The questions are summarized below.

Q. Has the tower blind spot been there since it was built? If so, why is this now a safety concern?

A. Although not considered "unsafe", the blind spot has been a safety concern for several years. Now that there is a proposed project to reconfigure the runway, it is a logical time to incorporate any safety recommendations that will enhance the operational safety of the airport.

Q. How close can the planes be to the adjacent homes during takeoff and landing?

A. The existing traffic pattern altitude for aircraft in the vicinity of Ann Arbor Municipal Airport is 1,000' above ground level. However, during the approach and departure phases of flight, aircraft do descend below this altitude. Actual flight profiles of various models of departing aircraft, including heights above Lohr Road, will be determined and provided at the next CAC meeting.

Q. Why does the airport need to allow for a 34:1 approach slope?

A. The runway approach slope over State Street has been 20:1 for quite some time. Since the current critical aircraft has been determined to be a B-II category jet, FAA Part 77 regulations specify the flatter 34:1 slope as the appropriate approach surface. The proposed 34:1 approach slope will provide approaching aircraft with greater vertical clearance over obstructions, and as a result, a greater margin of safety when operating in low-visibility conditions.

Throughout the meeting, several questions were raised that required additional follow-up information. These are the questions and a response.

Q. What makes the number of overruns "unusually high"? Can the data for the seven reported overruns be provided?

A. The data is still being compiled and will be made available on the Airport website in the upcoming weeks.

Q. How high will planes be over Lohr Road and the adjacent homes?

A. This analysis is ongoing. Results will be provided when they are available.

Q. Why is the 34:1 approach on State Street needed, particularly if State Street will not be widened in the immediate future?

A. The runway approach slope over State Street has been 20:1 for quite some time. Since the current critical aircraft has been determined to be a B-II category jet, FAA Part 77 regulations specify the flatter 34:1 slope as the appropriate approach surface. The proposed 34:1 approach slope will provide approaching aircraft with greater vertical clearance over obstructions, and as a result, a greater margin of safety when operating in low-visibility conditions.

Q. Has the justification for the improvements been fully examined?

A. The justification has been fully examined. The impetus for the improvements is to provide the recommended runway length for the Critical Aircraft that are currently using the airport, as well as the appropriate clear approach surfaces to Runway 6/24. The airport has documented well over 500 annual operations by type B-II aircraft, making this the current Critical Aircraft category. As documented in the Michigan Aviation System Plan (MASP 2008), and supported by FAA Advisory Circular 150/5325-4B, a runway length of 4,300 feet is recommended for category B-II aircraft, based on safety considerations.

Q. It was requested that a copy of the Michigan Airport System Plan (MASP) be provided.

A. A copy of the MASP can be obtained at:

www.michigan.gov/documents/aero/Cover_thru_**MASP**_study_team_MI_airport_system_plan_**MASP**_256781_7.pdf

Q. It was requested that documentation be provided that demonstrated the 500 operations by B-II aircraft.

A. MDOT is finalizing the User Survey Report. Once the report is completed, it will be posted on the Airport's website.

Q. It was also requested that a copy of the FAA Advisory Circular regarding runway length be provided.

A. The FAA AC 150/5325-4B, Runway Length Requirements for Airport Design can be found at: www.**faa**.gov/airports_airtraffic/airports/resources/**advisory_circular**s/media/150-5325-4B/150_5325_4b.doc.

Q. Does the logic/process that justifies the runway extension imply that there will be a continual "creep" in the length of the runway?

A. The decision to extend a runway always rests with the Airport Sponsor (in this case, the City of Ann Arbor). So even if there is a future change in Critical Aircraft category, and enough operations to justify further extension of the runway, neither the State nor the FAA would actually mandate that the extension take place. Since a future runway extension (beyond the proposed 4,300') would result in the shifting (and possibly enlarging) of the Runway Safety Areas and Runway Protection Zones beyond the existing airport boundaries, it is extremely unlikely that the City of Ann Arbor would pursue additional extension of Runway 6/24.

If this report does not agree with your records or understanding of this meeting, or if there are any questions, please advise the writer immediately in writing; otherwise, we will assume the comments to be correct.

DISCUSSION

This meeting summary provides an overview of the major topics and discussion items from the second Ann Arbor Municipal Airport Citizens Advisory Committee (CAC) meeting. This meeting summary is not intended to be a transcript of the meeting.

The second CAC meeting was held to discuss: 1) the environmental studies update (noise, historic resources, and botanical and wetland survey), 2) study justification and purpose and need, 3) study status and next steps, and 4) questions and answers.

Environmental Studies Update

Noise

The results of the noise analysis were presented by Mr. Dan Botto, URS. Mr. Botto provided a handout packet and three drawings illustrating noise contours (see attached). The noise analysis uses the Integrated Noise Model (INM), a methodology developed and approved by the Federal Aviation Administration (FAA). The INM is designed to estimate long-term average effects using average annual inputs, not the noise level of a single event.

The data used in the INM included aircraft operations, flight operations by aircraft type and time of day, runways and runway utilization, and flight tracks and flight track utilization. The data used in the model reflected 61,969 aircraft operations for 2009 and 69,717 aircraft operations for the future year 2014. It should be noted that the air taxi/commuter day/night split provided was incorrect. The actual and modeled day/night split for this category of flight operations is 100 percent of arrivals occur during the noise day period, while departures are 96 percent daytime and four percent nighttime. A list of aircraft operations was provided that was generated from Flight Explorer data and the MDOT User Survey.

The INM generated results for three scenarios: Base Year (2009), No Action (2014), and the proposed project (2014). Impacts are determined by comparing the future proposed project to the No Action. The analysis shows that noise impacts for the proposed project do not extend off of airport property; therefore, no impacts would occur to the adjacent properties. Refer to the attached handout and drawings for more detail.

Historic Resources

A review of historic resources was conducted by Commonwealth Cultural Resources Group (CCRG). CCRG completed a site file and literature search and a preliminary field survey. They looked at archaeological (below ground) and above-ground resources. The results of their review concluded there are no existing significant above-ground resources associated with the airport property. The analysis of the data for the below ground resources is pending. The results will be presented at the next CAC meeting.

Botanical and Wetland Survey

A botanical survey was completed by JJR in June of this year. During the site visit, an investigation was conducted for threatened or endangered species and general plant communities. The areas immediately surrounding the runway and the airport facilities are predominately either open field / lawn or agricultural fields. Currently over 160 acres of land owned by the airport are being farmed. Along the southern portion of the property, the area is forested, with some portions being a forested wetland. A drainage ditch passes through the airport. The vegetation along the ditch is mostly shrubs with some larger trees. We will be coordinating with the Washtenaw County Drain Commission to confirm county drain jurisdiction.

The wetland analysis is pending. MDEQ will be conducting a site visit and will make the final determination as to the presence of wetlands at the airport. The results will be presented at the next CAC meeting.

Study Justification / Purpose and Need

Mr. Mark Noel, MDOT, presented the results of the User Survey Report. He provided a handout (see attached). The Critical Aircraft as defined by FAA is the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. Based on the results of the user survey, the critical aircraft for the airport is a B-II, small aircraft.

According to FAA Advisory Circular 150/5325-4B, the recommended runway length for categroy B-II Small Aircraft is 4,200 feet. MDOT recommends 4,300 feet, based on the recommendations of the Michigan Airport System Plan (MASP 2008). The recommended runway lengths will allow most B-II Small classification aircraft to operate at their optimum capabilities without weight restrictions.

It was noted that the Airport Advisory Committee's purpose for the project incorporates safety improvements: runway extension to minimize overruns and a runway shift to address State Road approach and FAA tower line of sight. This purpose differs from FAA and MDOT justification for runway extension, which is based on providing the recommended runway length for the current critical aircraft of the airport. A formal purpose and need statement for the project is being developed in accordance with National Environmental Policy Act (NEPA) guidelines.

Study Status and Next Steps

The study team is currently working to prepare a first draft of the Environmental Assessment. The next CAC meeting will be in the fall and will focus on an environmental studies update for the remaining resource categories.

Overrun Data

A summary of the overrun data was provided to the group. Each CAC member in attendance was provided a copy of a summary table followed by a report for each overrun, if the report was available. The overrun data was compiled based on reported incidents in the FAA databases and other unreported incidents. There have been five reported overruns, four unreported overruns, and two that are unknown (undetermined whether aircraft went off the end of the runway or off the side of the runway).

Member Update
Each CAC member was asked to provide an update on what they have been hearing from their constituency. The following is a summary of what the members expressed as concerns or comments from their constituency:

- The editorials and op eds are not stating the truth.
- There is a mix of supporters and non-supporters. The non-supporters are concerned because of the impact on their quality of life.
- Is it possible to raise the tower to eliminate the line of sight issues?
- There have been questions about the funding source for the project.
- Some are concerned about the project and its potential impacts, but there have been more comments on the Argo Dam at this time.
- There is an organized group very strongly opposed to the project.
- Safety is primary concern. Fear that planes will crash into nearby homes.
- Concerned about the use of tax dollars to pay for the project.
- Concern that Pittsfield Township provides safety response and that Pittsfield tax dollars are being used for that.

Other Items Discussed
Throughout the meeting, CAC members asked questions regarding the information presented. A summary of the items is provided below.

- Four sources were used for the User Survey Report: (1) Flight Aware data, data from the two FBOs: (2) Solo Aviation and (3) Ann Arbor Aviation Center, and (4) based aircraft records.
- The noise analysis is computer generated based on aircraft types. Field measurements for noise were not conducted.
- The noise analysis models flight paths for both existing and future conditions, compensating for the proposed change in runway length.
- There are no trees being cut in St. James Woods.
- A negative economic effect that might occur if the runway is not extended is aircraft that use the airport with weight restrictions may need to land and refuel, or be required to operate with reduced cargo or reduced passengers.
- MDOT has been involved with this project since early 2007, when the City of Ann Arbor started the process to modify the ALP.
- The Itinerant (visiting) Aircraft operational information was collected by the two FBOs located on the airport. Sources were the pilot sign-in registration logs (Airport Registers) from each FBO.

One item discussed was the date of the last user survey and the previous critical aircraft. The consultant team was not able to provide a definite answer at the meeting. Based on a file review by MDOT, the following information was obtained.

In June 2008 MDOT approved an ALP dated April 2008 that indicates a Beech King Air (approach category B-II) is the design group. The previous ALP, dated 1994, was approved by MDOT in 1995 and indicated the design aircraft was approach category B-II. Prior to 1994, the ALP's MDOT has on file do not definitively identify the critical aircraft, except the 1957 ALP. This ALP identifies effective lengths for aircraft of current conditions (3,500 feet) and future conditions (4,300 feet).

If this report does not agree with your records or understanding of this meeting, or if there are any questions, please advise the writer immediately in writing; otherwise, we will assume the comments to be correct.

FAA Policy and Guidance for NEPA Compliance

FAA Order 1050.1E

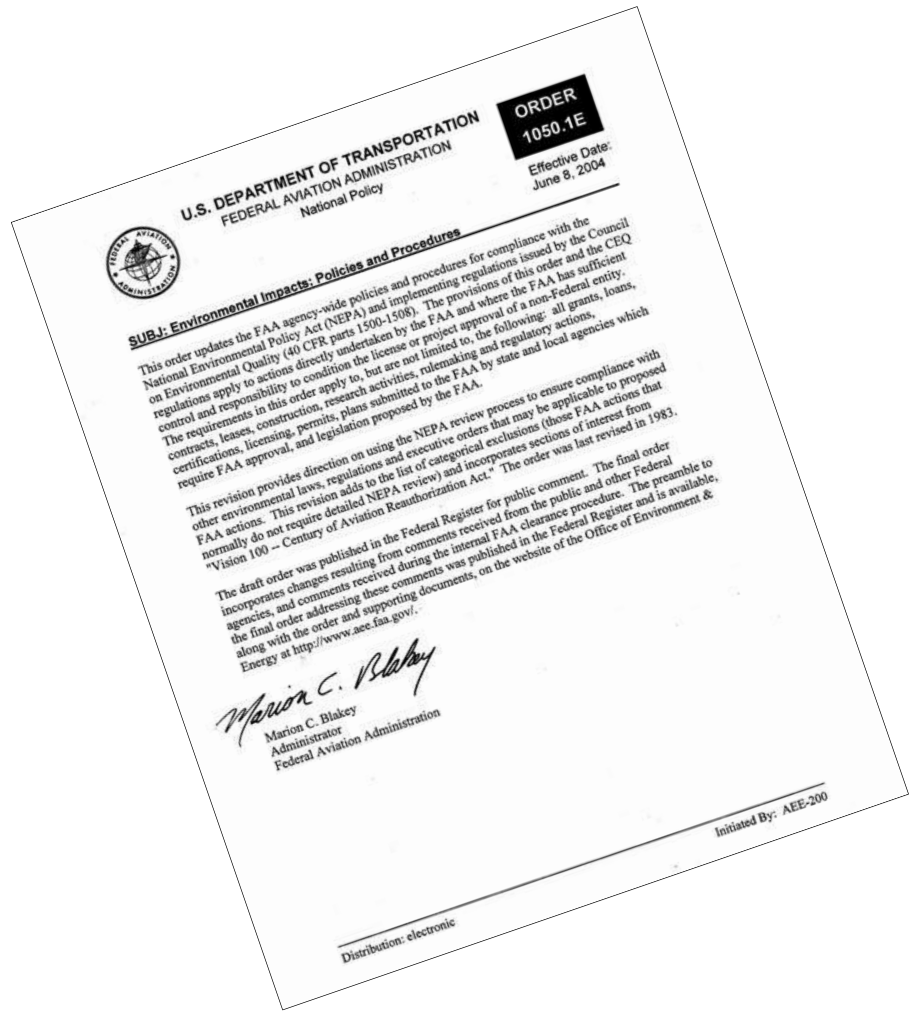
Environmental Impacts: Policies and Procedures

FAA Order 5050.4B

NEPA Implementing Instructions for Airport Actions

Title 14 CFR Part 150

Airport Noise Compatibility Planning



U.S. DEPARTMENT OF TRANSPORTATION
FEDERAL AVIATION ADMINISTRATION
National Policy

ORDER 1050.1E

Effective Date: June 8, 2004

SUBJ: Environmental Impacts: Policies and Procedures

This order updates the FAA agency-wide policies and procedures for compliance with the National Environmental Policy Act (NEPA) and implementing regulations issued by the Council on Environmental Quality (40 CFR parts 1500-1508). The provisions of this order and the CEQ regulations apply to actions directly undertaken by the FAA and where the FAA has sufficient control and responsibility to condition the license or project approval of a non-Federal entity. The requirements in this order apply to, but are not limited to, the following: all grants, loans, contracts, leases, construction, research activities, rulemaking and regulatory actions, certifications, licensing, permits, plans submitted to the FAA by state and local agencies which require FAA approval, and legislation proposed by the FAA.

This revision provides direction on using the NEPA review process to ensure compliance with other environmental laws, regulations and executive orders that may be applicable to proposed FAA actions. This revision adds to the list of categorical exclusions (those FAA actions that normally do not require detailed NEPA review) and incorporates sections of interest from "Vision 100 -- Century of Aviation Reauthorization Act." The order was last revised in 1983.

The draft order was published in the Federal Register for public comment. The final order incorporates changes resulting from comments received from the public and other Federal agencies, and comments received during the internal FAA clearance procedure. The preamble to the final order addressing these comments was published in the Federal Register and is available, along with the order and supporting documents, on the website of the Office of Environment & Energy at http://www.aee.faa.gov/.

Assessment of Aircraft Related Noise

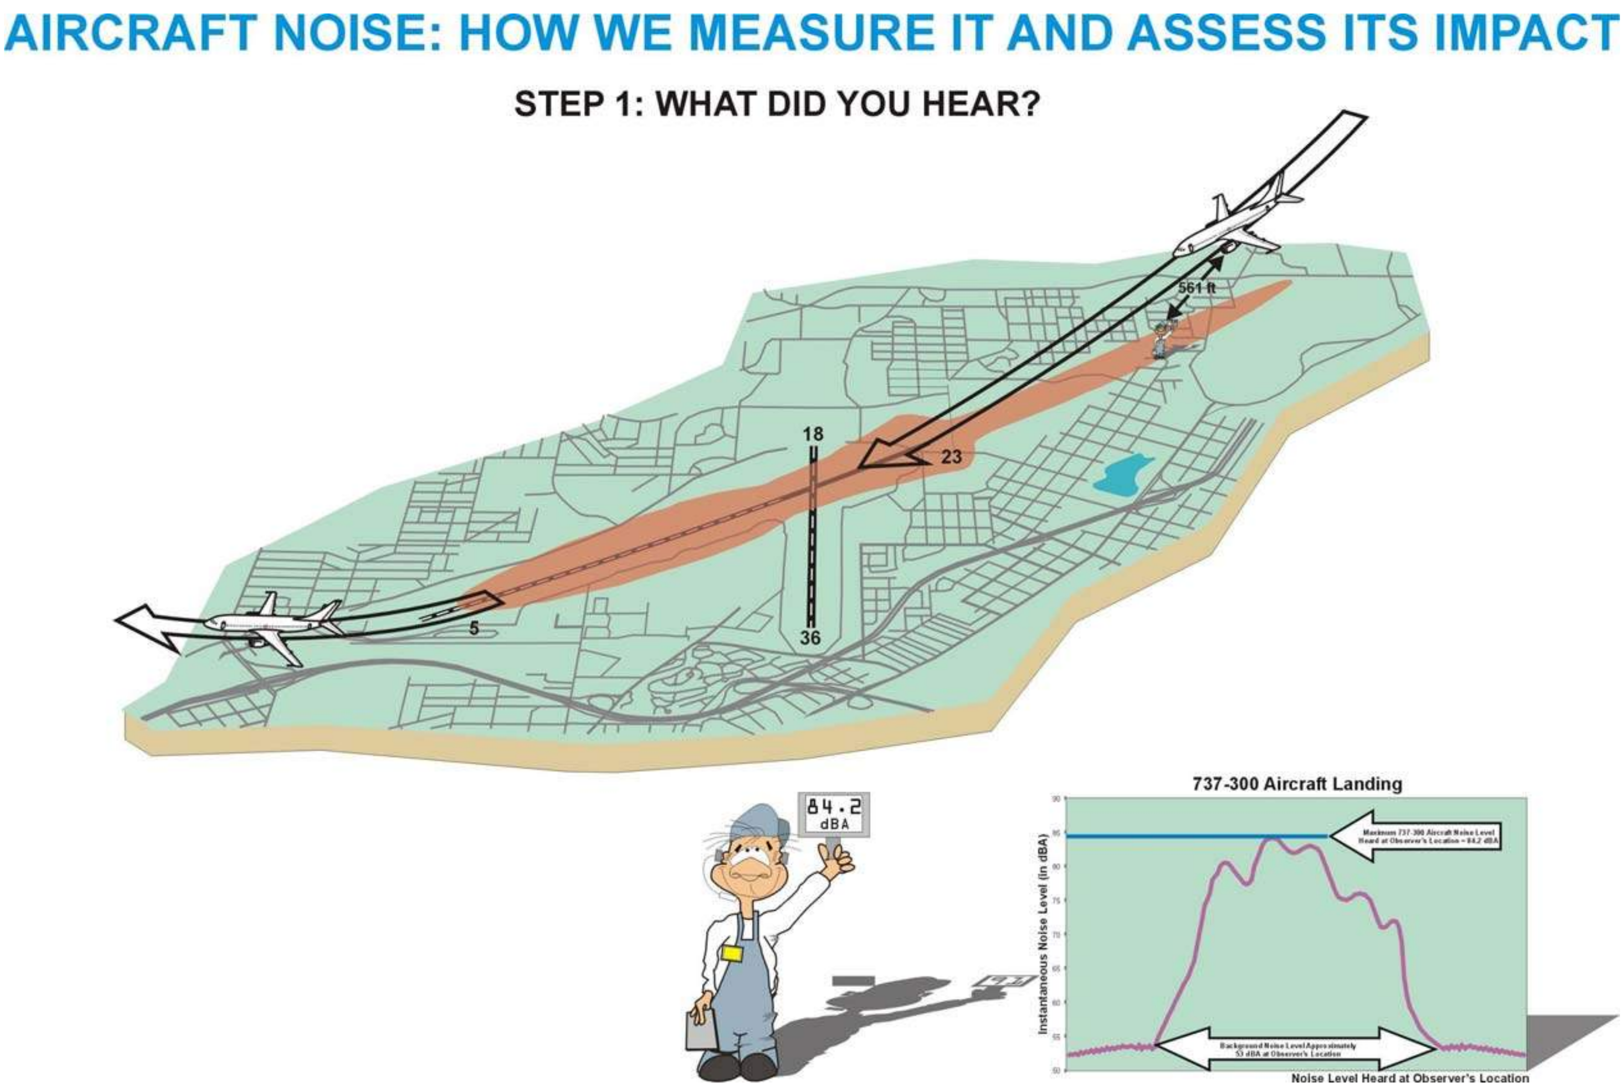
FAA Integrated Noise Model (INM) version 7.0a

- Has been distributed for use by the FAA since 1978
- Continual enhancements to stay consistent with evolving aircraft, technology, and best practices
- Required tool for FAR Part 150 Noise Compatibility Planning; Part 161 Approval of Airport Noise Restrictions; and FAA Order 1050 EA's and EIS's
- INM is an average value model designed to estimate long-term effects

Assessment of Aircraft Related Noise

- EA determines noise impacts on INM DNL contours
- Analysis will include:
  - Base year - 2009
  - Future year - 2014
    - With and without proposed project
  - Standard DNL Metric

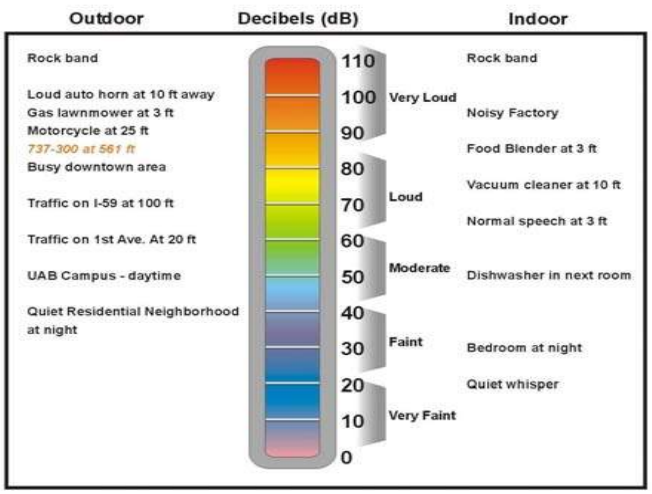
Aircraft Noise: How Do We Measure and Assess Impacts



Aircraft Noise: How Do We Measure and Assess Impacts

AIRCRAFT NOISE: HOW WE MEASURE IT AND ASSESS ITS IMPACT

STEP 2: HOW LOUD IS THAT?



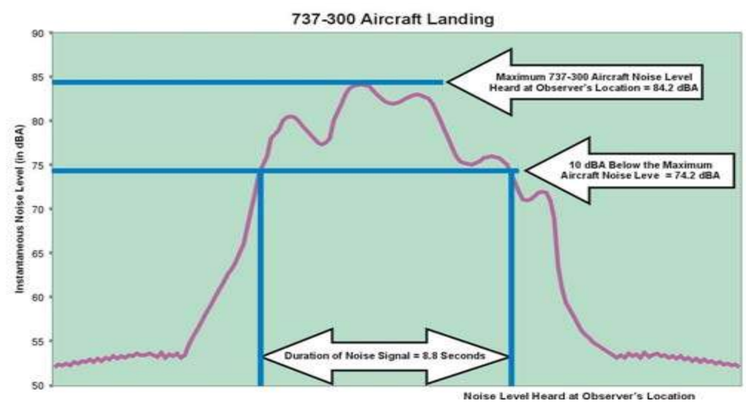
STEP 3: HOW LONG DID IT LAST?

The duration of an aircraft noise event is defined as the number of seconds between the first and last values of the instantaneous noise level which are a minimum of 10 dBA below the maximum aircraft noise level (Lmax).

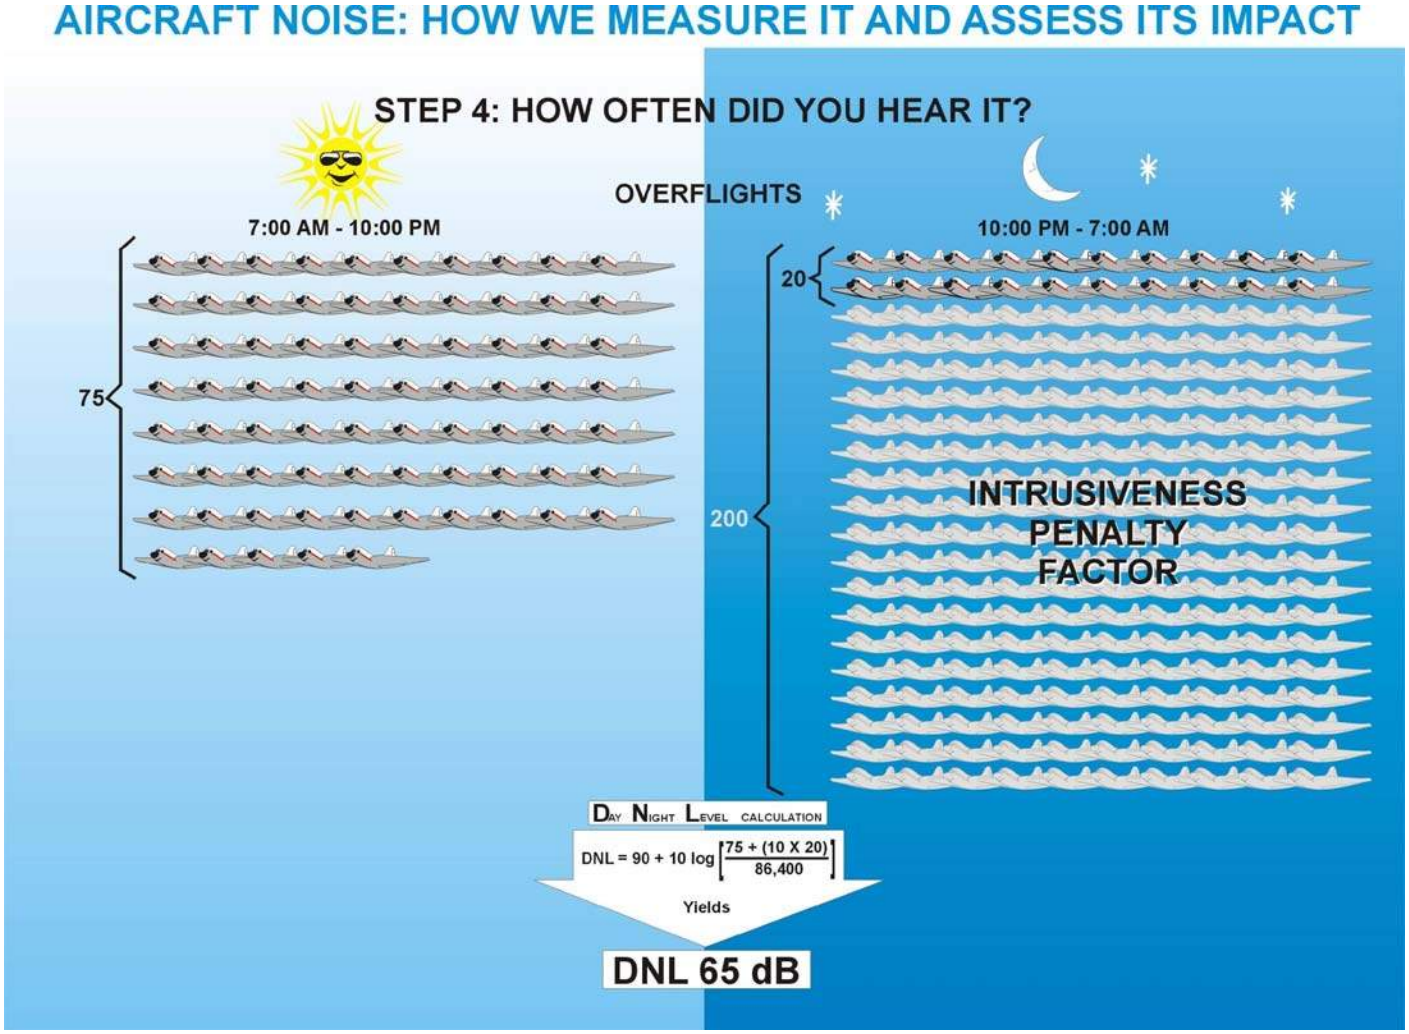
The Sound Exposure Level (SEL) describes with a single number the sound energy during an aircraft noise event. SEL takes into account both the duration and the magnitude of the aircraft noise event. The duration correction increases the magnitude in an attempt to account for the increased noisiness of sounds of long duration versus sounds of short duration. Because the duration of aircraft noise events are greater than one second, the numerical value of the SEL for an aircraft noise event is always greater than the numerical value of the maximum level, Lmax.

For Example:

Lmax = 84.2 dBA   Duration = 8.8 seconds   SEL = 90 dBA



Aircraft Noise: How Do We Measure and Assess Impacts



Noise Metric

- **Day-Night Average Sound Level (DNL)**:

DNL logarithmically averages aircraft sound levels at a location over a complete 24-hour period, with a 10-decibel adjustment added to those noise events occurring between 10:00 p.m. and 7:00 a.m. (local time) the following morning. Primary metric for airport noise impacts.

Noise Modeling Methodology

INM Input Data:

- Aircraft Operations
  - 2009 Base Year: FAA ATADS Data from April 08 through March 09
  - Forecast for Future Year 2014: FAA 2009 ARB TAF
- Flight Operations by Aircraft Type and Time of Day
  - From MDOT User's Survey and Flight Explorer® data
- Runways and Runway Utilization
  - From discussion with Air Traffic Control
- Flight Tracks and Flight Track Utilization
  - From discussion with Air Traffic Control and published flight procedures

Noise Modeling Methodology

INM Input Data:

- Aircraft Operations
  - 2009 Base Year: 61,969
  - Future Year 2014: 69,717
- Day / Night Split (Day 7:00 am to 9:59 pm, Night 10:00 pm to 6:59 am)
  - Air Taxi/Commuter: Arrivals 100% Day, Departures 96/4%
  - GA: Arrivals 95/5%, Departures 96/4%
- Flight Tracks:
  - Arrivals and departures are all straight in and straight out
  - Runways 06 and 12 have right turn patterns, Runways 24 and 30 have left turn patterns

Runway Utilization

Aircraft Type	Runway 06	Runway 24	Runway 12	Ruwnay 30

Assessment of Aircraft Related Noise Impacts in an Environmental Assessment

- Noise Exposure Contours at DNL 65, 70, and 75 dB
- No-Action and Proposed Project
- Average Annual Day: Daily average of annual operations
- **Impacts determined by**:

  Yearly Day/Night Average Sound Level (DNL)

Assessment of Aircraft Related Noise Impacts

- Impacts are determined by comparing future Proposed Project DNL contours to the No-action alternative DNL contour.
- Significant impact occurs at noise sensitive locations with an increase of 1.5 dB or greater within the DNL 65 Contour
- If significant impact exists, analysis within the DNL 60 for an increase of 3 dB or greater is required.

INM Output Data

- INM provides the following noise data for existing and future conditions for comparison purposes:
  - Noise contours (DNL 65, 70 and 75 dB)
  - Noise levels at identified noise sensitive sites (if necessary)
  - Noise levels in metrics other than DNL, such as L_{max}, L_{eq}, SEL, and Number of Events Above (if necessary)

CRITICAL AIRCRAFT:

The Critical Aircraft is defined by FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the Critical Aircraft weighs less than 60,000 lbs, a classification is used rather than a specific aircraft model.

Based on analysis of the recent User Survey at Ann Arbor Municipal Airport, the current Critical Aircraft classification has been determined to be a **B-II, Small Aircraft**. Aircraft in this category have approach speeds between 91 and 120 knots, wingspans between 49 and 78 feet, and have a maximum certificated takeoff weight of 12,500 lbs. or less.

A representative aircraft of this classification is the Beechcraft King Air 200, a twin-engine turboprop aircraft that typically seats 10-12 passengers, including crew.

AIRCRAFT CLASSIFICATION (FAA):

Approach Category:

Category A:	Approach speed less than 91 knots.
Category B:	Approach speed 91 to 120 knots.
Category C:	Approach speed 121 to 140 knots.
Category D:	Approach speed 141 to 165 knots.
Category E:	Approach speed 166 knots +

Design Group:

Group I:	Wingspan less than 49 feet.
Group II:	Wingspan 49 to 78 feet.
Group III:	Wingspan 79 to 117 feet.
Group IV:	Wingspan 118 to 170 feet.
Group V:	Wingspan 171 to 213 feet.
Group VI:	Wingspan 214 feet +

Small Airplane: An airplane of 12,500 lbs. or less maximum certificated takeoff weight.

Large Airplane: An airplane of more than 12,500 lbs. maximum certificated takeoff weight.

RUNWAY LENGTH RECOMMENDATIONS FOR B-II, SMALL AIRCRAFT:

MDOT – Michigan Airport System Plan (MASP 2008): **4,300 feet**
(statewide standard)

FAA – Advisory Circular 150/5325-4B,
"Runway Length Requirements for Airport Design" **4,200 feet** *
(airport-specific standard, from Figure 2-2)

* Note: Runway length obtained graphically from Figure 2-2. The following data for Ann Arbor Municipal Airport was used in the determination:
Airport Elevation: 839 feet above mean sea level
Temperature: 83 degrees F mean daily maximum temp of hottest month of year (July)

As stated in FAA Advisory Circular 150/5325-4B, "The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions." The Critical Aircraft is considered the regular use aircraft.

The recommended lengths listed above will allow most B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions), most of the time. Interstate commerce into and out of a community can be negatively impacted if business aircraft are forced to operate with load restrictions (i.e. reduced passengers, fuel, cargo) due to a shorter than recommended length primary runway.

The recommended lengths are also a safety enhancement, that not only provide enough runway for takeoff by a fully-loaded Critical Aircraft, but also provide additional runway for the purpose of bringing the aircraft to a stop in an aborted-takeoff situation. In takeoff situations where pilots detect a problem with the aircraft while on the takeoff roll, if there is not enough runway remaining to bring the aircraft to a stop, pilots are forced to continue the takeoff and deal with the problem in the air. By having enough remaining runway to safely abort a takeoff and bring the aircraft to a stop, a pilot would be able to avoid a potentially hazardous situation of taking to the air with a mechanically-deficient aircraft.

Citizens Advisory Committee Meeting

Ann Arbor Municipal Airport Environmental Assessment

February 22, 2010
3:00 pm – 4:30 pm

1.	Introductions	3:00 - 3:10
2.	Environmental Studies Update a. Wetland Resources b. Surface/Groundwater Resources c. Cultural Resources	3:10 - 3:20
3.	Study Justification a. Purpose and Need Summary b. User Survey Supplemental Report	3:20 - 3:40
4.	Study Status & Next Steps a. Departure Profile Analysis b. Next steps	3:40 - 4:00
5.	Discussion a. CAC member report	4:00 - 4:30

Information Packet – Citizens Advisory Council Meeting #3

Ann Arbor Municipal Airport Environmental Assessment

Prepared By: JJR

February 22, 2010

The JJR consultant team has completed investigations to assess existing conditions on airport property and its immediate vicinity for the following categories: noise analysis; land use; socioeconomics; air quality; historic resources; contaminated sites; Section 4(f) resources; and the physical and ecological environment. Data from these investigations is used as a base to identify potential impacts from proposed improvements at the airport. Potential mitigation measures to minimize impacts are also being addressed. Data collection has involved fieldwork, literature searches, and coordination with appropriate resource agencies.

The specific categories of studies are listed below along with a brief description and status of the analysis being completed.

Noise – The noise analysis compares the existing noise levels with future levels under two scenarios, a No Build Alternative and a Build Alternative. The Build Alternative assumes the proposed improvements are implemented at the airport. The results of this analysis are compared with the surrounding land use to ensure compatibility.

> ***Status:*** Completed. The noise analysis, which indicates that the Build Alternative is not expected to have any significant aircraft noise impacts, was presented at CAC Meeting #2.

Land Use – Existing land use data was collected and compared with any anticipated changes as a result of the proposed improvements at the airport. These changes were compared to the existing land use plans and future land use plans of City of Ann Arbor and surrounding municipalities.

> ***Status:*** Complete. Existing and proposed land use adjacent to and in the immediate vicinity of ARB is compatible with normal airport operations.

Socioeconomics – This category includes potential impacts on community displacements (residential and commercial) community cohesion, community facilities, demographics, economy, and environmental justice. Environmental justice considers impacts to low-income and minority populations with the intention of avoiding disproportionate impacts to these populations.

> ***Status:*** Complete. There would be no displacements or impacts to community cohesion, facilities, demographics or economy. There would be no impacts to low-income or minority populations.

Air Quality –The study team completed an assessment of the project in accordance with the FAA Air Quality Procedures for Civilian Airports & Air Force Bases (1997). Based on this assessment and prior studies on general aviation airports, the project is not expected to result in violations of National Ambient Air Quality Standards (NAAQS)

> ***Status:*** Complete. It is anticipated that agency coordination will continue through the environmental clearance phase.

Historic Resources – The study team evaluated cultural resources, both above-ground and below-ground including a review of the state archaeological site files and the state above-ground resource files to determine if there are any previously recorded cultural resources in or near the airport property.

> ***Status:*** Complete with a determination of no affect from the State Historic Preservation Office.

Contamination/Hazardous Materials – The study team researched environmental records including State and Federal databases of sites containing hazardous or contaminated materials to determine whether listed sites exist within the project area. The results of the database search have been summarized in relation to the potential for encountering hazardous or contaminated materials within the limits of the proposed improvements.

> ***Status:*** Complete. The proposed improvements are not anticipated to have an impact on known properties listed by state and/or federal agencies as either contaminated or sites of environmental concern.

Section 4(f) Resources - Section 4(f) of the Department of Transportation Act (1966) specifies that publicly-owned land, such as a park, recreational area, or wildlife and waterfowl refuge, of national, state, or local significance, or any land from a historic site of national, state, or local significance, may not be used for transportation projects unless there is no other prudent and feasible alternative.

> ***Status:*** Complete; no Section 4(f) resources will be affected by the proposed Build Alternative.

Physical and Ecological Environment- This category encompasses many resources, including water resources, biotic communities, threatened and endangered species, wetland resources, floodplains, and farmland.

> **Water Resources** –Based on a review of existing databases and fieldwork, the study team evaluated potential impacts to surface water and subsurface groundwater, including issues related to siltation, runoff, dredge and/or fill activities in navigable waters, aquifer or well contamination, and impacts on sensitive ecological areas.
>
> > ***Status:*** Complete. It is estimated that impervious surface resulting from the Build Alternative would increase slightly from the existing 7 percent to 7.4 percent of the site. Surface and subsurface groundwater resources would not be affected by the proposed improvements.
>
> **Biotic Communities –** Biotic communities that may be impacted by the proposed airport expansion were identified and characterized based on: 1) existing available data, 2) coordination with the U.S. Fish and Wildlife Service (FWS), the Michigan Department of Natural Resources (MDNR), and Michigan Department of Environmental Quality (MDEQ), and 3) and fieldwork.
>
> > ***Status:*** Complete. No existing natural biotic communities would be impacted by the proposed Build Alternative.

Threatened and Endangered Species – The study team coordinated with the U.S. Fish and Wildlife Service and the Michigan Natural Features Inventory to determine if there are any known threatened or endangered species protected under Federal and/or State jurisdiction within the project area. One state endangered and one state special concern bird species has been observed in the vicinity of the project area.

> ***Status:*** Complete. ARB is coordinating with the Audubon Society to identify restricted mowing areas during breeding seasons for these species.

Wetlands – Wetlands were identified through a review of National Wetland Inventory maps, the county soil survey, USGS topographical maps and a field investigation. The Michigan Department of Environmental Quality (MDEQ) completed a field review of the property on July, 21, 2010 to delineate wetlands in the vicinity of proposed improvements.

> ***Status:*** Complete. The Build Alternative would have no wetland impact. The results of the MDEQ investigation will be presented at the February 22, 2010 CAC meeting.

Floodplains – The study team reviewed Federal Emergency Management Administration (FEMA) flood boundary maps for the existing stream on the property.

> ***Status:*** Completed. No grading or fill is proposed within the floodplain boundary.

Farmland –Impacts to prime and unique farmland, and farmland of state or local significance were determined through a review of county soil maps and coordination with the U.S. Department of Agriculture Natural Resources Conservation Service (NRCS), Michigan Department of Agriculture, and the MDNR. Form AD1006 was completed and submitted to the NRCS for determination of impacts to prime or important agricultural soils.

> ***Status:*** The completed Form AD1006 has been reviewed by the Washtenaw County NRCS with a determination of no impacts to prime and unique farmlands resulting from this project.

Light Emissions – Light emissions were evaluated based on the location and type of airfield lighting proposed and proximity to these land uses.

> ***Status:*** Completed. Impacts from light emissions are not considered significant. New lights would be directed upwards and LED units would be used where appropriate.

Draft Section 2. Purpose and Need

Section 2.
Purpose and Need

2.1 PROJECT LOCATION AND DESCRIPTION

Note: The following information contains a large number of aviation-related acronyms. A glossary with definitions is included in Section 10 of this document.

Ann Arbor Municipal Airport (ARB) is a public-use, general aviation airport located in Washtenaw County, Michigan. The airport is located in Pittsfield Township and consists of approximately 837 acres. ARB is generally bound by Ellsworth Road to the north, State Road to the east, and Lohr Road to the west (Figure 2-1).

ARB is in close proximity to state highways including US-23, M-14, US-12, and I-94. Direct access to the airport is from Ellsworth and State Roads. The closest public-use airport is Willow Run Airport in Ypsilanti, which is approximately 12 miles to the east (approximately a 20 minute drive by automobile). The southeastern region of Michigan has a high level of commerce, and high levels of commercial, corporate, and general aviation air traffic.

The City of Ann Arbor owns and operates ARB. The city is responsible for contracting with the Fixed Base Operators (FBO), which are Solo Aviation, Ann Arbor Aviation Center, and Bijan Air. ARB's operating budget is an enterprise fund comprised solely of revenue generated by airport operations.

The primary runway, Runway 6/24, is 3,505-feet long by 75-feet wide and is oriented in a northeast/southwest direction. ARB has 22 permanent aviation service buildings, including the administration building, the FBOs, maintenance facilities, conventional box hangars, a privately owned hangar, and the FAA Air Traffic Control Tower (ATCT). The airport also provides 150 T-hangar spaces in an additional 13 T-hangar structures.

The current FAA-approved Airport Layout Plan (ALP) was updated in 2008 (Figure 2-2), and it incorporates the future development proposed in the Airport Capital Improvement Plan for ARB.

The proposed improvements from the ALP that are documented in this EA include:

- Shift and extend existing Runway 6/24, resulting in a runway that would be 4,300-feet long by 75-feet wide.
- Shift and extend the parallel taxiway to coincide with the revised Runway 6/24.
- Provide a new taxiway connector to the extended Runway 6 end.
- Provide a new taxiway connector and holding bay to the shifted Runway 24 end.

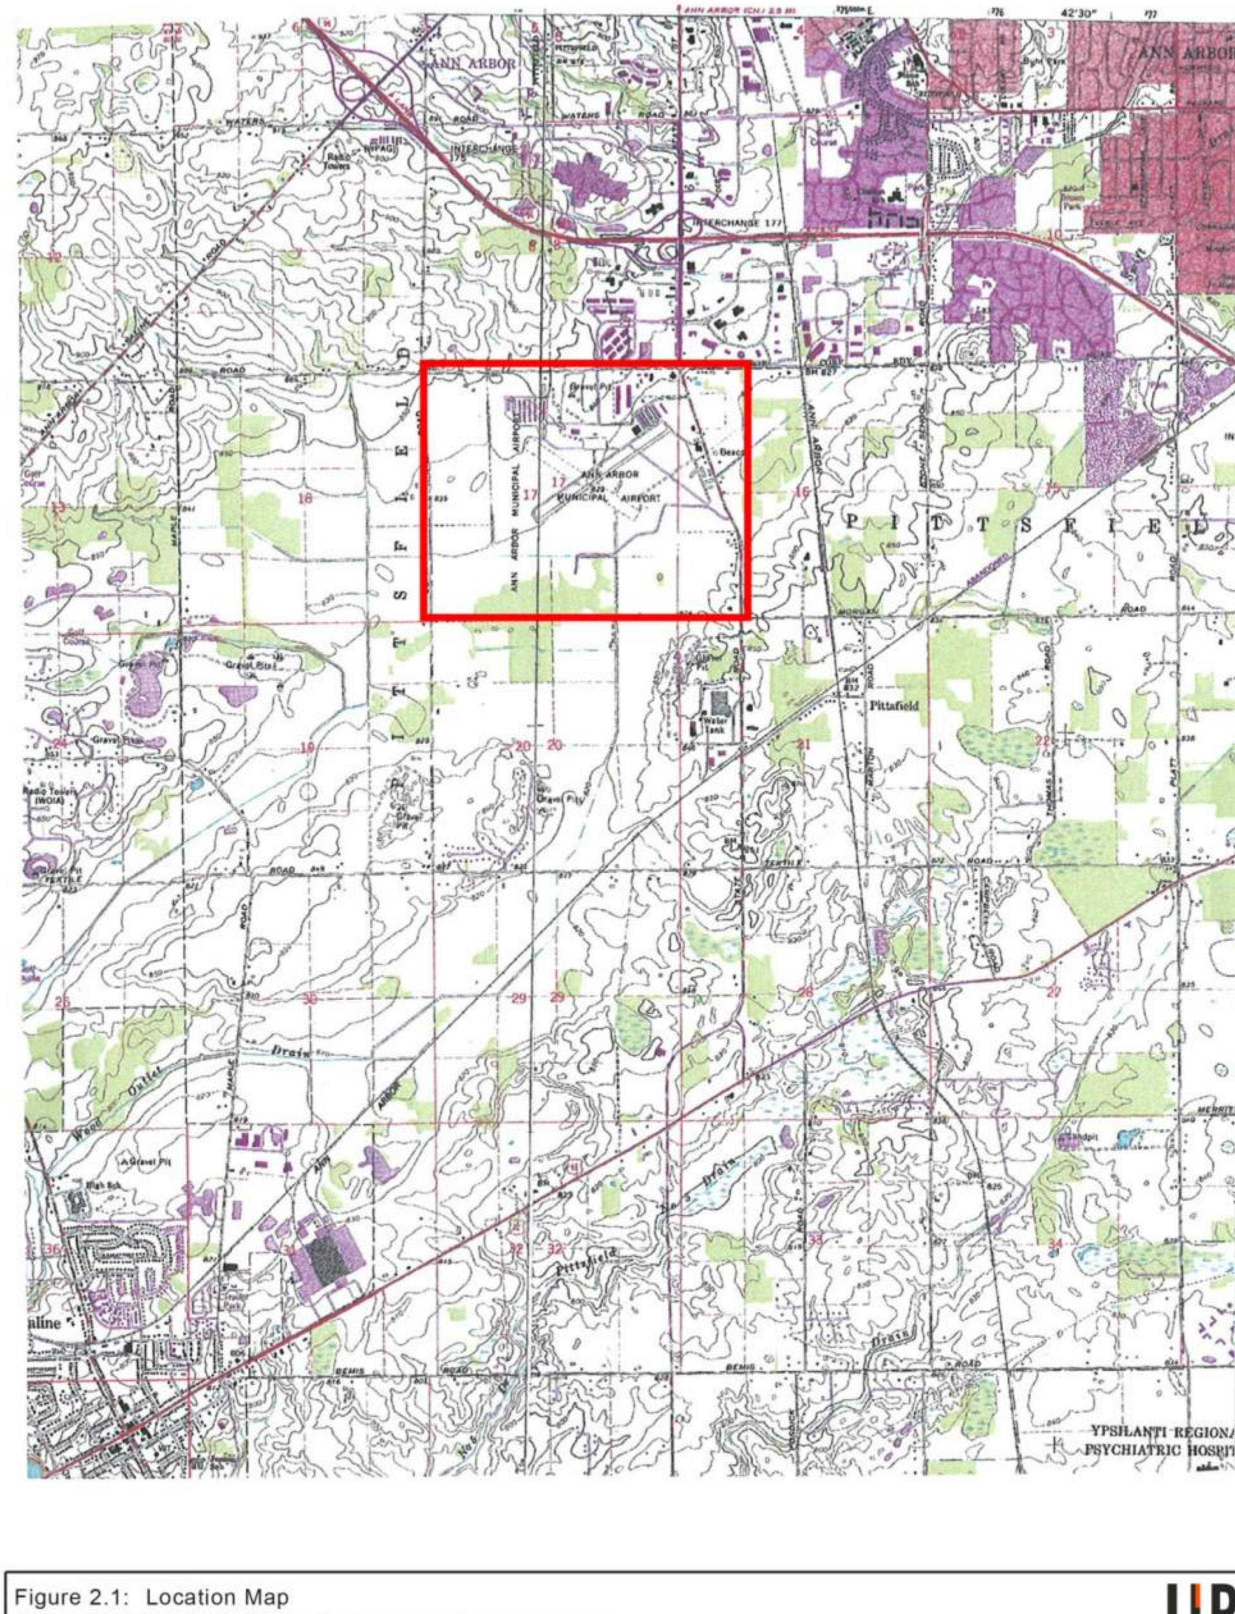

Figure 2.1: Location Map
Ann Arbor Municipal Airport Environmental Assessment

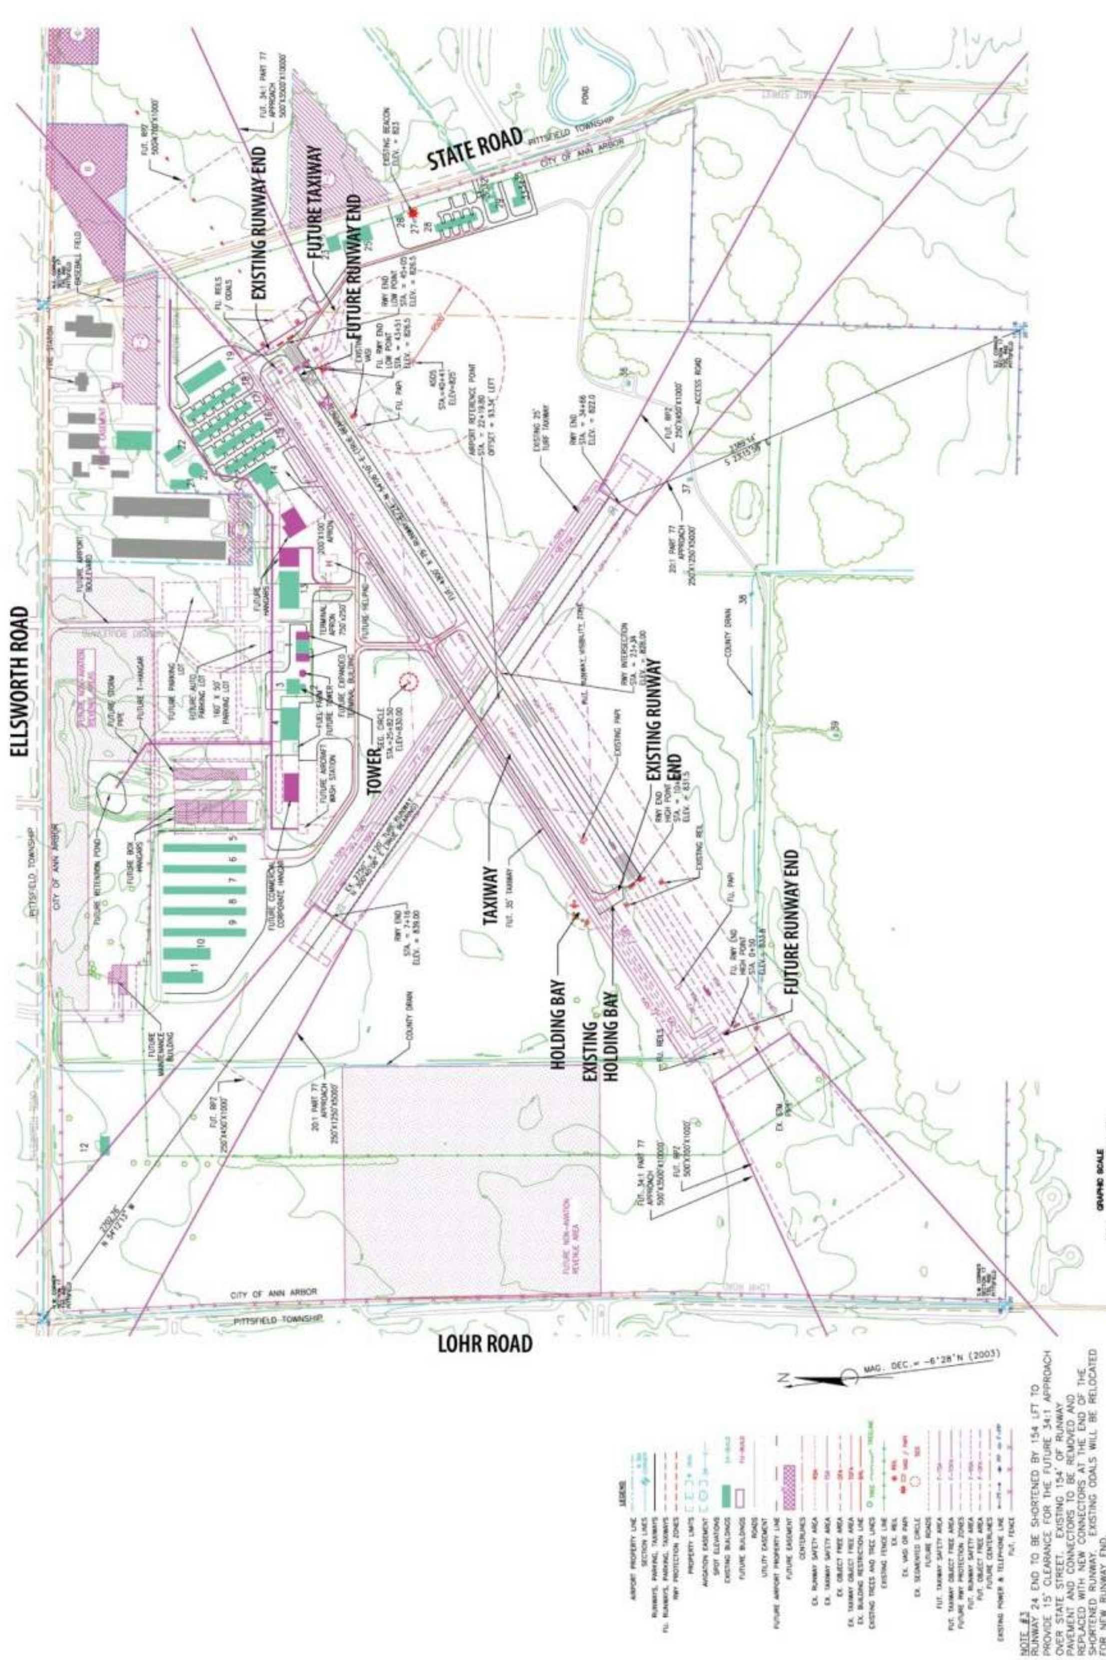

Figure 2.2: Airport Layout Plan
Ann Arbor Municipal Airport Environmental Assessment

2.2 PURPOSE AND NEED

The purpose of the proposed improvements at ARB is to provide facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport.

The critical aircraft is defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the critical aircraft weigh less than 60,000 lbs, a classification of aircraft is used rather than a specific individual aircraft model.

A recent Airport User Survey has confirmed that the critical aircraft classification for ARB is "B-II Small Aircraft" (MDOT, 2009). Aircrafts in this category have runway approach speeds between 91 and 120 knots, wingspans between 49- and 79-feet, and maximum certificated takeoff weights of 12,500 lbs or less. A representative aircraft of this classification is the Beechcraft King Air 200, a twin-engine turboprop aircraft that typically seats 10-12 people, including the flight crew.

As stated in FAA Advisory Circular 150/5325-4B, "*The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions*." Airplanes that are classified within an airport's critical aircraft classification are considered by the FAA to be the regular use aircrafts of the primary runway.

Development of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions). Interstate commerce into and out of a community can be negatively impacted if business aircraft are forced to operate with load restrictions (i.e. reductions in passengers, cargo, and fuel associated with aircraft range) due to lack of suitable runway length.

An origin-destination analysis was conducted on Instrument Flight Rules (IFR) flight plan records associated with ARB as part of the user survey process. Although the data analyzed did not include records of all operations conducted at ARB, it did confirm that there are a significant number of operations between ARB and distant locations throughout the country.

Flight operations were verified between ARB and at least 31 other states (approximately 63 percent of the continental US). Also, approximately 67 percent of the IFR flight plan records examined were between ARB and out-of-state locations. These factors are strong indicators of corporate flight activity associated with interstate commerce, as opposed to local pleasure flying by general aviation pilots. The large number of states that were linked to ARB is also a strong indicator of use of the airport by many corporations, as opposed to a single or few corporate users. Some of the larger corporations that were confirmed by the user survey as being users of ARB are Synergy International, Wells Fargo, Polaris Industries, Bombardier Aerospace, Avis Industrial Corporation, Thumb Energy, NetJets, and AvFuel. NetJets provides on-demand air charter service and corporate aircraft fractional ownership opportunities to a large number of businesses located throughout the country. AvFuel Corporation, a nationwide supplier of aviation fuels and aviation support services, is headquartered in Ann Arbor and bases their Cessna 560 Excel Jet at ARB.

The City of Ann Arbor proposes to extend the existing 3,505-foot primary runway to 4,300-feet in total length in order to more effectively accommodate the critical aircraft that currently use the airport. The runway extension would enhance interstate commerce associated with business aviation, and the other proposed modifications would enhance the operational safety of ARB.

The objectives of the proposed project are to:

- Enhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions.
- Enhance operational safety by improving the FAA ATCT line-of-sight issues.
- Enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road.
- Reduce the occurrence of runway overrun incidents by small category A-I aircraft (local objective).
- Relocate and potentially upgrade the Runway 24 Approach Light System.

2.2.1 Safety Enhancement

The proposed 150-foot shift of the Runway 24 threshold to the west would enhance the safety of ground operations by taxiing aircraft. Currently, a hangar structure blocks the line-of-sight from the FAA ATCT to a portion of the parallel taxiway at the east end of the runway, including most of the taxiway hold area for departing aircrafts. While this situation is not considered hazardous, the proposed shift would enhance operational safety, and possibly prevent a runway incursion, by expanding the view of the hold area and parallel taxiway to ATCT personnel.

The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles. This is particularly beneficial when aircraft are operating in low-visibility conditions. Provision of a clear 34:1 approach surface would also potentially allow visibility minimums to the Instrument Approach Procedure to Runway 24 to be lowered to 3/4 of a mile, as opposed to the current 1-mile visibility minimum. This would enhance the all-weather capability of the airport (and also interstate commerce) by allowing aircraft to continue to access the airport when weather conditions resulted in visibility dropping below the current 1-mile minimum.

Due to the proposed relocation of the Runway 24 threshold, it is also proposed that the existing runway approach light system be relocated accordingly. The airport currently uses an Omni-Directional Approach Lighting System (ODALS) to identify the approach end of Runway 24. The sequentially-flashing strobe lights assist pilots in identifying the runway threshold location and runway centerline alignment in low-visibility conditions. Since the FAA no longer installs ODALS, the current approach light system would potentially be upgraded and replaced with the newer Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF) as part of the relocation. The MALSF would serve the same function as the ODALS, and is structurally very similar.

2.2.2 Role of the Airport

ARB is a public-use facility that serves the local community by supporting economic development and public services. The following businesses and organizations are located at and operate from the airport and employ staff that supports the operations of the airport:

- Two fixed-wing FBOs;
- A helicopter FBO;
- Three national rental car agencies;
- Two flying clubs;
- Four flight schools and pilot training centers;
- FAA ATCT; and,
- Air taxi, aircraft sales, aviation insurance and aviation fueling businesses.

ARB serves the Ann Arbor medical and biomedical industries with professional air ambulance services, transporting patients, human organs, radio isotopes, and other biomedical products and services.

Community pilots and aircraft owners are members of nonprofit organizations providing "no charge" charitable gifts of flight time to citizens in need. Some of these organizations include Wings of Mercy, Angel Flight, and Dreams and Wings. Wings of Mercy has documented 292 fights into or out of ARB since 1992 including 51 flights in 2009.

ARB is included in the FAA's National Plan of Integrated Airport Systems (NPIAS) as a general aviation airport. Not all public-use airports are included in this nationwide airport system plan. Inclusion in the NPIAS signifies that the FAA considers this airport an important part of the nation's air transportation system, and it makes ARB eligible to receive federal grants as part of the FAA's Airport Improvement Program.

ARB is also included in MDOT's Michigan Airport System Plan (MASP) (MDOT, 2008). The MASP presents the results of an airport system planning process that has been aligned with the goals and objectives of MDOT's State Long Range Plan. The MASP supports programming decisions and is useful in evaluating programming actions related to airport system and airport facility deficiencies.

As part of the MASP development, each of Michigan's public-use airports were assigned to one of three tiers based on their contribution to the state system goals. Tier 1 airports respond to essential/critical airport system goals. These airports should be developed to their full and appropriate level. Tier 2 airports complement the essential/critical airport system and/or respond to local community needs. Focus at these airports should be on maintaining infrastructure with a lesser emphasis on facility expansion. Tier 3 airports duplicate services provided by other airports and/or respond to specific needs of individuals and small business.

The MASP identifies ARB as a Tier 1 airport, with a current MASP classification of B-II. Basic standard developmental items for B-II category airports, as outlined in Table 40 of the MASP, are a paved primary runway of 4,300-feet in length by 75-feet wide, a paved parallel taxiway, appropriate runway lighting and visual aids, a runway approach protection plan, basic pilot and aircraft services, all-weather access, year-round access, and landside access. Although it is not a requirement, MDOT encourages all of Michigan's Tier 1 airport sponsors to consider development of their airports to comply with the basic development standards outlined in the MASP.

ARB currently meets all MASP basic development standards for category B-II airports, with the exception of runway length. The current primary runway is only 3,505-feet in length by 75-feet wide. An extension of the primary runway to 4,300-feet in length would result in the airport meeting all state-recommended standards for B-II category airports.

2.2.3 Aircraft Operations and Runway Length Recommendations

The Airport Reference Code (ARC) is a coding system developed by the FAA to correlate airport design criteria with the operational and physical characteristics of the airplane types that regularly use a particular airport. The critical aircraft, or grouping of aircraft, are generally the largest, most demanding types that conduct at least 500 operations per year at the airport. The ARC for each particular airport is determined based on two characteristics of the critical aircraft: the approach speed to the runway and the wingspan of the aircraft.

The first component, designated by letter A through E, is the critical aircraft's Approach Category. This is determined by the approach speed to the runway:

- Category A: Approach speed less than 91 knots.
- Category B: Approach speed 91 knots or more, but less than 121 knots.
- Category C: Approach speed 121 knots or more, but less than 141 knots.
- Category D: Approach speed 141 knots or more, but less than 166 knots.
- Category E: Approach speed 166 knots or more.

The second component, designated by Roman numeral I through VI, is the critical aircraft's Design Group. This is determined by the wingspan of the aircraft:

- Group I: Wingspan less than 49-feet.
- Group II: Wingspan 49-feet or more, but less than 79-feet.
- Group III: Wingspan 79-feet or more, but less than 118-feet.
- Group IV: Wingspan 118-feet or more, but less than 171-feet.
- Group V: Wingspan 171-feet or more, but less than 214-feet.
- Group VI: Wingspan 214-feet or more, but less than 261-feet.

The FAA has also established categories for aircraft based on their certificated Maximum Takeoff Weights (MTOW), which are determined by each specific aircraft's manufacturer. *Small Aircraft* are those with MTOWs of 12,500 lbs. or less. *Large Aircraft* are those with MTOWs greater than 12,500 lbs.

As previously mentioned, the airport user survey confirmed that the current critical aircraft category (and ARC) for ARB is "**B-II Small Aircraft**". Based on the findings of the user survey analysis, the primary runway length recommendations by MDOT and FAA are as follows:

MDOT – *Source: Michigan Airport System Plan (MASP 2008)* **4,300-feet**
Table 40 (*statewide standard for all ARC B-II airports*)

FAA – *Source: FAA Advisory Circular 150/5325-4B,* **4,200-feet***
"Runway Length Requirements for Airport Design"
Figure 2-2 (*airport-specific standard for ARB*)

* *Note: The FAA runway length recommendation was obtained from Figure 2-2 in Advisory Circular 150/5325-4B. The following specifics for ARB were used in the determination:*
Airport Elevation: 839-feet above mean sea level
Temperature: 83 degrees F mean daily maximum temp, hottest month of year (July)

The FAA recommended runway length of 4,200-feet at ARB was obtained by calculation from FAA Advisory Circular 150/5325-4B, *"Runway Length Requirements for Airport Design"*, a publication that is used nationally by the agency. The resulting recommended runway lengths are airport-specific, and can vary by hundreds of-feet from site to site, depending on the specific airport elevations and mean daily maximum temperatures used in the calculations.

The MDOT recommendation of 4,300-feet is a statewide standard for all airports in the state with category B-II critical aircraft classifications. Since airport elevations and mean maximum temperatures do not vary significantly from airport to airport in Michigan, as opposed to many other states, MDOT uses a single runway length recommendation for all airports of the same critical aircraft classification.

The existing ARC shown on the current ALP for the airport is category B-II. This classification has been confirmed correct by the recent airport user survey. Even if the proposed extension to 4,300-feet is constructed, the ALP shows that the future ARC for the airport will remain category B-II.

2.2.4 Airport Operational Forecasts

Year 2007 was the onset year of planning activities associated with the potential extension of Runway 6/24, and the year in which the airport manager and FBOs were requested to collect based and itinerant aircraft operational data for the purpose of determining project justification. In order to maintain consistency, FlightAware operational records from target year 2007 were also examined during the user survey analytical process.

Actual total operations for year 2009 were recently published (January 2010) by the FAA for airports with ATCT. From the user survey operational data year 2007 through the most recent operational data year 2009, total annual operations at ARB have decreased approximately 21.8%

(from 72,853 actual in 2007 to 57,004 actual in 2009). Since the operational totals were obtained from actual ATCT records, rather than estimates, they are considered very accurate.

By applying the 21.8% decrease in total annual operations at ARB from 2007 to 2009 to the user survey results, a very accurate estimate can be obtained for the current level of operations by B-II category critical aircraft. The user survey report documents a total of 750 actual annual operations by B-II category critical aircraft from survey data year 2007. A 21.8% decrease in this number is 586 - still well above the FAA's substantial use threshold of 500. Therefore, even with the current decrease in annual operations due to the economic recession, there is still justification at the present time for the runway extension.

The FAA's Terminal Area Forecast (TAF) shows year 2009 to be a low-point in total annual operations at ARB. The TAF projects total annual operations to continually increase every single year, from year 2010 through year 2030. Since the estimated 586 annual operations by B-II category aircraft in year 2009 confirm present justification for the runway extension, the continual increase in operations that are forecasted by the TAF confirm that justification for the runway extension is substantiated through year 2030.

The following actual and forecasted Total Operations at ARB, from year 2000 through year 2030, are from the FAA data sources listed below. The Estimated Category B-II Operations for each year have been calculated based on the percentage of actual B-II operations to actual total operations in survey data year 2007.

Table 2-1
Actual and Forecasted Total Operations at ARB

Year	Total Operations	Estimated Category B-II Operations
2000	104,342 *	1,074
2001	102,321 *	1,053
2002	91,414 *	941
2003	77,051 *	793
2004	65,516 *	674
2005	67,940 *	699
2006	71,785 *	739
2007	72,853 *	750***
2008	64,910 *	668
2009	57,004 *	586
2010	56,986 **	586
2010	57,514 **	592
2012	58,073 **	598
2013	58,639 **	604
2014	59,212 **	610
2015	59,791 **	616
2016	60,376 **	622
2017	60,968 **	628
2018	61,567 **	634
2019	62,173 **	640
2020	62,786 **	646
2021	63,405 **	653
2022	64,032 **	659
2023	64,666 **	666
2024	65,307 **	672
2025	65,956 **	679
2026	66,613 **	686
2027	67,277 **	693
2028	67,948 **	700
2029	68,627 **	706
2030	69,314 **	714

* = Actual Total Operations from FAA ATCT records
** = Forecasted Total Operations from FAA TAF
*** = Actual (from User Survey)

Forecasts from the MDOT MASP also project increasing total operations at ARB from years 2010 through 2030. The MDOT forecasts, which are independent of the FAA forecasts, further substantiate the mid-term and long-term FAA projections of a rebound in activity at ARB to near survey year 2007 operational levels.

AvFuel Corporation, which bases a B-II Large category Citation 560 Excel jet at ARB, has confirmed in writing that their operations at ARB increased from 211 actual operations in 2007 to 223 actual operations in 2008. Their Chief Pilot has also submitted written documentation that forecasts their future operational levels potentially increasing to 350 to 450 operations per year at ARB.

The FAA TAF forecast, MDOT MASP forecast, and AvFuel's operational forecast all provide support to the fact that survey year 2007 operational data that was analyzed in the user survey process is a very pertinent representation of estimated future operational levels at ARB.

2.2.5 Surrounding Land Uses

ARB is bordered by Ellsworth Road to the north, Lohr Road to the west, and State Road to the east. The primary runway is situated in a northeast/southwest direction. Residential, business, industrial, recreational, agricultural, and forested areas are located adjacent to the airport, and efforts were made during the analysis of alternatives to minimize impacts to these resources. Residential properties are located along Lohr Road and business properties are located along State and Ellsworth Roads. A perennial stream crosses through the airport property and flows to the south connecting to a county drain (Wood Outlet). A portion of the stream near the southwest end of the runway is enclosed in a concrete culvert.

2.2.6 Other Considerations

Aircraft performance information and runway length requirements for each airplane are contained in the individual airplane flight operating manual. As quoted from FAA Advisory Circular 150/5325-4B, Paragraph 206, "*This information is provided to assist the airplane operator in determining the runway length necessary to operate safely. Performance information from those manuals was selectively grouped and used to develop the runway length curves in Figures 2-1 and 2-2. The major parameters utilized for the development of these curves were the takeoff and landing distances for Figure 2-1 and the takeoff, landing, and accelerate-stop distances for Figure 2-2*." As stated earlier in this section, Figure 2-2 of the Advisory Circular was used to determine the FAA-recommended runway length for ARB.

The *accelerate-stop distance* concept referred to above is an important operating consideration. In this concept, the pilot not only considers the amount of runway needed for takeoff, but also the amount of runway needed to abort the takeoff while on the takeoff roll and bring the aircraft to a stop. In situations where pilots detect a problem with the aircraft while on the takeoff roll, they are forced to continue the takeoff and contend with the problem in the air if there is not enough runway remaining to bring the aircraft to a stop. By having enough remaining runway to safely abort a takeoff and stop the aircraft while still on the ground, a pilot would be able to avoid a potentially hazardous situation of taking to the air with a mechanically-deficient aircraft.

A local objective is to reduce the occurrence of runway overrun incidents. While overrun incidents are not officially recognized by the FAA or MDOT as justification for extending runways, there is merit to this local objective. The 11 overrun incident reports that were analyzed showed that most runway overruns at ARB involved small single-engine category A-I aircraft. These types of incidents often involve student pilots or low-time, relatively inexperienced pilots. There is no evidence in the incident reports that any of the aircraft which overran the end of the existing 3,505-foot runway exceeded the limits of the 300-foot long turf Runway Safety Area. Therefore, in each of these cases, the proposed 4,300-foot long runway would have provided sufficient length for the small category A-I aircraft to safely come to a stop while still on the runway pavement, without running off the runway end.

The considerations mentioned above do not imply that the existing 3,505-foot runway is unsafe in any regard. Accelerate-stop distance requirements can be accommodated on the existing runway if pilots of critical category aircraft operate at reduced load capacities. In the cases of the previous runway overrun incidents, the turf Runway Safety Areas to the existing runway performed as designed and provided a clear area for the overrunning aircraft to come to a stop. There were no reports of personal injuries, although there were reports of aircraft damage in several of the incidents.

2.2.7 Summary

The proposed shift and extension of primary Runway 6/24 at ARB would provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility. The proposed project would satisfy the FAA design objective of providing sufficient runway length to allow airplanes that regularly use it to operate without weight restrictions. The proposed project would also result in ARB achieving full compliance with all MDOT basic developmental standards outlined in the MASP 2008 for category B-II airports.

In particular, the proposed project would provide the following benefits:

- Enhance business aviation and interstate commerce by providing sufficient runway length to allow the majority of category B-II Small critical aircraft that currently use ARB to operate without load restrictions (i.e. reduction in passengers, cargo, and fuel associated with aircraft range).
- Enhance the safety of ground operations, and lessen the chances of a runway incursion, by expanding the view of the parallel taxiway and aircraft hold area to ATCT personnel.
- Improve the all-weather capability of ARB and enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24.
- Address the local objective of decreasing the number of runway overruns by small category A-I aircraft by providing approximately 800-feet of additional runway pavement.

Airport User Survey Supplemental Report

SUPPLEMENTAL REPORT
AIRPORT USER SURVEY

ANN ARBOR MUNICIPAL AIRPORT (ARB)
ANN ARBOR, MICHIGAN

December 2009

This Supplemental Report is associated with the original Airport User Survey Report for Ann Arbor Municipal Airport (ARB), dated July 2009. The information contained in this supplement provides additional details and updates to the information contained in the original report.

Additional analysis of the aircraft operational data has resulted in the generation of supplemental information, three new exhibits, and updates to the numbers of annual operations performed by category B-II critical aircraft. The following paragraphs explain in detail the information provided in the new exhibits, as well as the supplemental information and updates to the operational numbers listed in the original user survey report.

<u>EXHIBIT No. 1</u>: ***Annual Operations Analysis by Specific Aircraft Model***

This exhibit shows annual operations at ARB by specific aircraft model, rather than only by their FAA aircraft classification as shown in the original user survey report. The various aircraft models are listed in three separate tables, based upon groupings of their FAA classifications (B-II, C-I, and C-II).

Supplemental data associated with annual operations by the Beechcraft King Air C90 has been included in the B-II category table of this exhibit. Operations by this particular model of aircraft were not included in the original July 2009 Airport User Survey Report.

<u>EXHIBIT No. 2</u>: ***Origin / Destination Analysis by State***

Exhibit No. 2 shows the results of an origin and destination analysis of aircraft operations conducted at ARB, based on examination of the FlightAware database from survey year 2007. Although 274 of the operations had aircraft model and ownership information blocked from the database at the aircraft owner's request, the origin and destination cities of each flight were still included.

The first column of the table shown in this exhibit lists 31 states (and Washington DC) from which operations into ARB originated, or operations out of ARB were going to as a destination. The second column lists operations attributed to each state by the 274 total operations with blocked aircraft and ownership records. The third and fourth columns list operations attributed to each state by B-II Small and B-II Large category aircraft. The last column lists the total number of operations attributed to each state.

The numbers of operations associated with each state are from the FlightAware Instrument Flight Rule (IFR) flight plan database only, and do not include records of all itinerant operations between ARB and other states. Nonetheless, the numbers shown in this exhibit confirm that in 2007, flight operations were conducted between ARB and at least 31 other states (approximately 63% of the continental US). Also, approximately 67% of the IFR flight records for the category B-II critical aircraft were between ARB and out-of-state locations. These factors confirm that there is a significant amount of flight operations being conducted at ARB that are either going to, or coming from, distant locations in other states.

EXHIBIT No. 3: *Small 10-Seat Aircraft Analysis*

The table in this exhibit lists *Small* aircraft models (less than or equal to 12,500 lbs. maximum certificated takeoff weight) that have 10 or more passenger seats, and that conducted operations at ARB in survey year 2007. The numbers of annual operations listed in the table are from the FlightAware IFR flight plan database only, and do not include records of all operations by aircraft of this type. The FlightAware records show that there were 425 annual operations by Small 10-seat or higher aircraft.

Exhibit No. 3 also shows that there were 211 annual operations by *Large* category (greater than 12,500 lbs. maximum certificated takeoff weight) B-II aircraft from the Based Aircraft data source and another 85 annual operations by Large category B-II aircraft from the FlightAware data source. The number of annual operations performed by the Small 10-seat or higher aircraft and the Large category aircraft combined is shown as 721.

The operational numbers listed in Exhibit No. 3 do not include blocked FlightAware operations, Visual Flight Rule (VFR) operations, or operations logged by pilots on the Fixed Base Operator (FBO) airport registers. Although the information shown is only a partial representation of all applicable aircraft, the 721 annual operations that were substantiated significantly confirm that Figure 2-2 in FAA Advisory Circular 150/5325-4B is the appropriate chart to reference in the determination of the FAA-recommended runway length of 4,200 feet at ARB.

UPDATED BASED AIRCRAFT ANALYSIS:

The Based Aircraft Analysis of the original user survey report listed 200 estimated annual operations by AvFuel's B-II Large category aircraft (see page 3 of the original report). AvFuel's Chief Pilot has since confirmed in writing that the actual number of operations by their Cessna Citation XL 560 aircraft at ARB over the past three calendar years has been 224 operations in 2006, 211 operations in 2007, and 223 operations in 2008.

In order to maintain consistency with the other survey year 2007 operational records analyzed, Exhibit No. 1 of this Supplemental Report shows the 211 actual annual operations by this aircraft in the "Based Aircraft Data Source" column of the category B-II table, instead of the original estimate of 200.

UPDATED ITINERANT AIRCRAFT ANALYSIS: (FBO Data Sources)

Itinerant (visiting) aircraft operational data that was evaluated as part of the original user survey analysis was obtained from the pilot registration logs (airport registers) of two of the airport's FBOs - Solo Aviation and Ann Arbor Aviation Center. Data was examined for a six-month survey time frame, and cross-checked against FlightAware records in order to prevent counting the same aircraft twice. Any operations that were already included in the FlightAware records were not included in the operational totals that were generated from the FBO records.

The FBO records provided 40 additional operations by B-II and greater category aircraft (32 by category B-II aircraft, 6 by category C-I aircraft, and 2 by category C-II aircraft). Since this data was based on a six-month time frame instead of the full calendar year 2007, these 40 actual operations were prorated into an estimated equivalent annual rate of 80 operations. The additional 40 estimated operations were the only operations in the original user survey analysis that were obtained by prorating actual partial-year data into an estimated equivalent annual rate.

As part of the supplemental analysis, estimated operations that were originally generated as a result of prorating partial-year data were not considered in the determination of the annual operations at ARB. This eliminates the potential effect of seasonal variation in flight activity levels negatively influencing annual operational estimates. Only the 40 actual operations that were documented by the FBOs as having occurred within the six-month survey period were counted as valid operations, since they did in fact occur in 2007. No operations were attributed to the remaining six months.

Exhibit No. 1 of this supplemental report shows only the 40 actual documented operations (32 by category B-II aircraft, 6 by category C-I aircraft, and 2 by category C-II aircraft) in the column that is labeled "2 FBO Register Data Sources".

UPDATED FLIGHTAWARE DATABASE ANALYSIS:

The FlightAware database analysis that was performed for the original July 2009 Airport User Survey Report resulted in the determination of 265 actual annual operations by B-II Small aircraft, and another 85 actual annual operations by B-II Large aircraft (see page 6 of the original report). However, the resulting numbers did not include operations by the Beechcraft King Air C90 model.

The King Air C90 is a B-II Small category aircraft, with a wingspan of 50'3". Earlier versions of the King Air 90 models (A90 and B90) have wingspans of less than 49', and are therefore category B-I Small aircraft. Since the FlightAware records that were originally analyzed for ARB did not include information which identified the specific model of each King Air 90 operation, no operations by King Air 90s were included in the original user survey analysis and report.

Although the FlightAware records do not provide information regarding the specific model of each King Air 90 operation listed, they do provide the aircraft registration N-number of each aircraft. By entering the N-number into the computerized FAA aircraft registration database, the specific model of each King Air 90 operation was able to be determined. A total of 157 operations by the B-II Small category King Air C90 model have been identified, out of 220 operations by King Air 90 models of all types.

Exhibit No. 1 of this supplemental report shows the 157 King Air C90 operations included in the "Flight Aware Data Source" column of the category B-II table. By adding these operations to the 265 operations by B-II Small aircraft and 85 operations by B-II Large aircraft that were previously identified in the original user survey report, the updated total number of actual annual operations by B-II category aircraft obtained from the FlightAware data source is 507.

The FlightAware database also confirmed usage of the airport by many large corporations, in addition to AvFuel, which is the only one actually based at ARB. Some of the other corporate users of ARB include Synergy International, Wells Fargo, Polaris Industries, Bombardier Aerospace, Avis Industrial Corporation, Thumb Energy, and NetJets. NetJets provides on-demand air charter services and corporate aircraft fractional ownership opportunities to a large number of other corporations that are located throughout the country.

AIRCRAFT OPERATIONAL FORECASTS:

Year 2007 was the onset year of the current planning activities associated with the potential extension of Runway 6/24. At that time, the airport manager and FBOs were requested to collect based and itinerant aircraft operational data over the course of year 2007 for the purpose of determining project justification. This data was reviewed during the user survey analysis, which was conducted in early 2009.

FlightAware records for any given year are not published until that particular calendar year has ended, and all operations that took place during the course of that year counted. Since the user survey analysis was conducted in early 2009, the most current operational records available at the time from FlightAware were associated with calendar year 2008. Although year 2008 records were available, year 2007 records from FlightAware were used in the user survey analytical process. This was due to the importance of maintaining consistency of year of operational records in the analysis, and not combining operational data collected by the airport manager and FBOs over year 2007 with the more recent FlightAware records from year 2008. The FlightAware records, airport manager records, and FBO records from calendar year 2007 that were used in the user survey analysis were all only one-year old at the time, and still considered valid for use in determining project justification.

The FAA Terminal Area Forecast (TAF) does project a short-term approximate 22% decrease in total annual operations at ARB from user survey year 2007 through year 2009 (from 72,895 actual in 2007 to 56,956 estimated for 2009). However, beginning in year 2010, the TAF projects continuously increasing annual operations at ARB, from the year 2009 low-point through year 2030. Itinerant annual operations are even projected to surpass survey year 2007 levels prior to the end of the 2030 forecast period.

Even if the worst case short-term projected 22% decrease in total annual operations is applied to the user survey results, there is still significant justification for the runway extension. The user survey report documents a total of 750 actual annual operations by B-II category critical aircraft that justify the runway extension. A 22% decrease in this number is 585 - still well above the FAA's substantial use threshold of 500. And again, beginning in 2010, operations at ARB are projected by the FAA to begin increasing every single year from that point forward, through year 2030.

Forecasts from the MDOT Michigan Airport System Plan (MASP 2008) also project increasing itinerant and total operations at ARB from years 2010 through 2030. The MDOT forecasts further substantiate the mid-term and long-term FAA projections of a rebound in current operational activity at ARB to survey year 2007 levels.

AvFuel Corporation, which bases a B-II Large category Citation 560 Excel jet at ARB, has confirmed that their operations at ARB actually increased from 211 operations in 2007 to 223 operations in 2008. Their Chief Pilot estimates that their future operational levels could potentially increase to 350 to 450 operations per year at ARB.

The FAA TAF forecast, MDOT MASP forecast, and AvFuel's operational forecasts all provide support to the fact that survey year 2007 operational data is a very pertinent representation of estimated future operational levels at ARB.

SUMMARY:

The supplemental analysis that was conducted after publication of the July 2009 Airport User Survey Report has resulted in additional justification in support of extension of Runway 6/24 to 4,300' in length.

Further analysis of the FlightAware IFR flight plan database has confirmed 507 actual operations at ARB in survey year 2007 by B-II category aircraft. This number does not include operations in the FlightAware records with aircraft information blocked at the owner's request, or VFR operations that were conducted without flight plans. Judging by the high number of out-of-state origin and destination locations of operations listed in the blocked category (see Exhibit No. 2), it is very likely that many of the associated aircraft were of the B-II or greater categories. Therefore, actual operations at ARB by aircraft of these categories are likely considerably higher than the 507 substantiated operations obtained from the FlightAware database.

The 507 actual operations by B-II category aircraft that were obtained from the FlightAware database also do not include operations conducted by AvFuel's based Cessna Citation XL 560, or operations obtained from the two FBO airport registers. AvFuel has confirmed 211 actual operations at ARB in 2007 with their B-II category aircraft, and data provided by the FBOs has confirmed 32 actual operations in 2007 by B-II category aircraft.

In summary, the supplemental analysis of this user survey has confirmed a total of 750 actual annual operations at ARB by category B-II aircraft. FlightAware records also confirmed that operations by aircraft in this critical aircraft category were performed by many large corporations, some of which are listed on page 4 of this report.

CONCLUSION:

In the majority of airport user survey processes, determinations and recommendations are issued based on analysis of estimated annual operations obtained from various airport users. In conducting the user survey at ARB, the analysis focused on evaluation of actual annual operations performed at the airport. This is obviously a much more accurate method of calculating the total number of annual operations associated with the determination of the critical aircraft and Airport Reference Code. It also eliminates the possibility of an airport user inflating their estimated operational numbers, in the hopes of obtaining a longer runway that is not truly justified.

While the numbers listed in this report do not include every operation that occurred at ARB in survey year 2007 with B-II category aircraft, they do confirm substantial usage of the airport by aircraft of this critical aircraft category. The Origin/Destination Analysis has shown a significant number of operations between ARB and distant out-of-state locations, which is a very good indicator of corporate activity associated with interstate commerce, as opposed to pleasure flying by general aviation pilots. FlightAware records also confirmed usage of the airport by many large corporations.

The information contained in this Supplemental Report provides additional justification in support of the findings and recommendations of the original July 2009 Airport User Survey Report. The user survey analysis has shown that justification for the proposed extension of primary Runway 6/24 to 4,300-feet has been confirmed, and the proposed project has been determined to be eligible to receive state and federal funding.

Although justification for the proposed project has been substantiated according to current MDOT and FAA standards associated with runway length recommendations, neither agency requires that the runway be extended. It is ultimately – and entirely – the decision of the city of Ann Arbor whether or not to proceed with the development of the project.

ANN ARBOR MUNICIPAL AIRPORT USER SURVEY - SUPPLEMENTAL REPORT - DECEMBER 2009

EXHIBIT NO. 1

ANNUAL OPERATIONS ANALYSIS BY SPECIFIC AIRCRAFT MODEL

Aircraft Model	FAA Approach Category	FAA Design Group	FAA Weight Class	Seating	Maximum Takeoff Weight (lbs.)	Aircraft Engine Type	Flight-Aware Data Source	Based Aircraft Data Source	2 FBO Register Data Sources	Total Annual Operations by Model
Aero Commander 695	B	II	Small	<10	<12,500	Multi-Eng	4	0	0	4
Beechcraft King Air C90	B	II	Small	10+	<12,500	Multi-Eng	157	0	0	157
Beechcraft King Air 100	B	II	Small	10+	<12,500	Multi-Eng	39	0	2	41
Beechcraft King Air 200	B	II	Small	10+	<12,500	Multi-Eng	215	0	8	223
Cessna 441 Conquest II	B	II	Small	<10	<12,500	Multi-Eng	7	0	4	11
Beechcraft King Air 300	B	II	Large	10+	12,500+	Multi-Eng	11	0	8	19
Beechcraft King Air 350	B	II	Large	10+	12,500+	Multi-Eng	43	0	4	47
Cessna Citation II 550	B	II	Large	<10	12,500+	Jet	6	0	2	8
Cessna Citation XL 560	B	II	Large	<10	12,500+	Jet	25	211	2	238
Cessna Citation 680	B	II	Large	<10	12,500+	Jet	0	0	2	2
Total B-II Category Annual Operations							507	211	32	750

Aircraft Model	FAA Approach Category	FAA Design Group	FAA Weight Class	Seating	Maximum Takeoff Weight (lbs.)	Aircraft Engine Type	Flight-Aware Data Source	Based Aircraft Data Source	2 FBO Register Data Sources	Total Annual Operations by Model
Learjet 25	C	I	Large	<10	12,500+	Jet	0	0	2	2
Learjet 31	C	I	Large	<10	12,500+	Jet	0	0	2	2
Learjet 45	C	I	Large	<10	12,500+	Jet	0	0	2	2
Total C-I Category Annual Operations							0	0	6	6

Aircraft Model	FAA Approach Category	FAA Design Group	FAA Weight Class	Seating	Maximum Takeoff Weight (lbs.)	Aircraft Engine Type	Flight-Aware Data Source	Based Aircraft Data Source	2 FBO Register Data Sources	Total Annual Operations by Model
IAI Westwind 1125	C	II	Large	<10	12,500+	Jet	0	0	2	4
Total C-II Category Annual Operations							0	0	2	4

CRITICAL AIRCRAFT CATEGORY DETERMINATION: B-II (Based on 750 Total Annual Operations by Aircraft of this Category)

NOTE: The annual operations listed in the above tables are ACTUAL documented operations from calendar year 2007.
The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.
Operations recorded by the FBOs and listed above represent only a partial-year (six-month) time frame.

A total of 274 operations in the FlightAware database had aircraft model and ownership information blocked at the owner's request.
As a result, their operational numbers are NOT included in the information shown above.
Judging by the high number of out-of-state origin and destination locations of aircraft in the blocked category (see Exhibit No. 2),
it is very likely that many of the associated aircraft were of the B-II and greater categories.
Therefore, actual operations at ARB by aircraft of these categories are likely considerably higher than the numbers shown above.

EXHIBIT NO. 2 ORIGIN / DESTINATION ANALYSIS BY STATE

Origin / Destination Analysis of IFR Aircraft Operations Between ARB and Other States (Records from FlightAware 2007 Database)

	STATE	Aircraft Type & Category Blocked	B-II Small Category	B-II Large Category	Totals by State
1	Alabama	0	1	0	1
2	Arizona	1	0	0	1
3	Arkansas	2	1	0	3
4	Connecticut	5	2	0	7
5	Florida	29	3	3	35
6	Georgia	5	6	12	23
7	Illinois	25	64	5	94
8	Indiana	6	21	1	28
9	Iowa	1	20	3	24
10	Kansas	3	0	0	3
11	Kentucky	2	13	0	15
12	Maine	2	0	0	2
13	Maryland	1	3	7	11
14	Massachusetts	5	0	1	6
15	**Michigan**	**79**	**162**	**20**	**261**
16	Minnesota	2	3	2	7
17	Missouri	0	5	0	5
18	Nebraska	3	0	1	4
19	New Hampshire	1	2	0	3
20	New Jersey	9	2	4	15
21	New York	6	5	1	12
22	North Carolina	4	1	1	6
23	Ohio	16	38	13	67
24	Pennsylvania	14	23	4	41
25	South Carolina	0	4	0	4
26	South Dakota	4	18	0	22
27	Tennessee	2	5	0	7
28	Texas	30	0	0	30
29	Virginia	1	3	0	4
30	Washington DC	5	1	2	8
31	West Virginia	1	7	0	8
32	Wisconsin	10	9	4	23
	No Record	0	0	1	1
	Totals by Category	**274**	**422**	**85**	**781**

IFR Aircraft Operation Totals by Category:

Within Michigan	79	162	20	261
Outside of Michigan	195	260	64	519
No Record	0	0	1	1

NOTE: The numbers of operations listed above are ACTUAL documented operations from calendar year 2007. The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.

The numbers shown above are from the FlightAware IFR Flight Plan Database only, and do NOT include records of all itinerant operations between ARB and other states. Nonetheless, the numbers shown above confirm that in 2007, flight operations were conducted between ARB and at least 31 other states and Washington DC (approx 63% of the continental US). Approximately 67% of these IFR flight records were between ARB and out-of-state locations.

EXHIBIT NO. 3 SMALL 10-SEAT AIRCRAFT ANALYSIS

Small Airplanes Having 10 or More Passenger Seats (Records from FlightAware 2007 Database)							
Aircraft Model	FAA Approach Category	FAA Design Group	FAA Weight Class	Seating	Maximum Takeoff Weight	Aircraft Engine Type	Annual Operations
Cessna Caravan 208	A	II	Small	10+	<12,500	Single-Eng	11
Swearingen Merlin III	B	I	Small	10+	<12,500	Multi-Eng	3
Beechcraft King Air C90	B	II	Small	10+	<12,500	Multi-Eng	157
Beechcraft King Air 100	B	II	Small	10+	<12,500	Multi-Eng	39
Beechcraft King Air 200	B	II	Small	10+	<12,500	Multi-Eng	215

Total Small 10-Seat Aircraft Annual Operations **425**

Total B-II Large Category Aircraft Annual Operations

Based Aircraft Data Source (B-II Large): **211**
FlightAware Data Source (B-II Large): **85**

Grand Total Annual Operations at ARB Applicable to Figure 2-2 in FAA Advisory Circular 150/5325-4B: **721**

NOTE: The annual operations listed above are ACTUAL documented operations from canendar year 2007.
The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.

The numbers shown in the table above are from the FlightAware IFR Flight Plan Database only, and do NOT include records of all small aircraft operations at ARB with 10-seat or greater aircraft models. Nonetheless, the above analysis confirms that Figure 2-2 in FAA AC 150/5325-4B is the appropriate chart to reference in the determination of the FAA-recommended runway length for Ann Arbor Municipal Airport.

Exhibit 14

FOR FURTHER INFORMATION CONTACT: Copies of the applications are available for inspection in the Records Center, East Building, PHH–30, 1200 New Jersey Avenue, Southeast, Washington, DC or at *http://regulations.gov.*

This notice of receipt of applications for special permit is published in accordance with Part 107 of the Federal hazardous materials transportation law (49 U.S.C. 5117(b); 49 CFR 1.53(b)).

Issued in Washington, DC, on March 11, 2010.

Delmer F. Billings,

Director, Office of Hazardous Materials, Special Permits and Approvals.

NEW SPECIAL PERMITS

Application No.	Docket No.	Applicant	Regulation(s) affected	Nature of special permits thereof
14977–N	....	Air Products and Chemicals, Inc. Allentown, PA.	49 CFR 173.301(f)	To authorize the transportation in commerce of certain DOT Specification 3T cylinders containing Silane without pressure relief devices by motor vehicle and cargo vessel. (modes 1, 3).
14978–N	....	Air Products and Chemicals, Inc. Allentown, PA.	49 CFR 173.181	To authorize the transportation in commerce of pyrophoric liquids in inner metal containers (bubblers) with openings greater than 25mm (1 inch) which are engineered to specific electronics applications that require a larger opening. (modes 1, 3).
149979–N	....	M & N Aviation, Carolina Inc.	49 CFR 172.101 Column (9B).	To authorize the air transportation in commerce of certain explosives which are forbidden or exceed quantity limits for shipment by cargo-only aircraft. (mode 4).
14980–N	....	Fisk Tank Carrier, Inc. Columbus, WI.	49 CFR 173.315 (j)(4)	To authorize the one-way transportation in commerce of certain non-DOT specification storage tanks containing propane. (mode 1).
14981–N	....	Eclipse Aerospace, Inc. (EAI) Albuquerque, NM.	49 CFR 173.309(b)	To authorize the manufacture, marking, sale and use of non-DOT specification cylinders for use as fire extinguishers. (modes 1, 2, 3, 4, 5).

BILLING CODE 4909–60–M

DEPARTMENT OF TRANSPORTATION

Federal Aviation Administration

Notice of Availability of Draft Environmental Assessment; Ann Arbor Municipal Airport, Ann Arbor, MI

AGENCY: The Federal Aviation Administration is issuing this notice on behalf of the Michigan Department of Transportation (MDOT), Bureau of Aeronautics and Freight Services.

ACTION: Notice of Availability of a Draft Environmental Assessment (EA) for public review and comment.

SUMMARY: The FAA has delegated selected responsibilities for compliance with the National Environmental Protection Act to the MDOT as part of the State Block Grant Agreement authorized under Title 49 U.S.C., Section 47128. This notice is to advise the public pursuant to the National Environmental Policy Act of 1969, as amended, (NEPA) 42 U.S.C. 4332(2)(c) that MDOT has prepared a Draft EA for the proposed extension of runway 6/24 at the Ann Arbor Municipal Airport. While not required for an EA, the FAA is issuing this notice to facilitate public involvement. The Draft EA assesses the potential environmental impacts resulting from the proposed extension of runway 6/24 from 3,500 feet to 4,300 feet. This evaluation also includes the relocation or replacement of the Federally Owned Omni Directional Approach Lighting System. All reasonable alternatives were considered including the no action alternative.

DATES: Written comments on the Draft EA must be received by MDOT on or before 5:00 p.m. on April 12, 2010. Comments may be sent by electronic mail to Molly Lamrouex at *lamrouexm@michigan.gov* or written comments may be submitted to Molly Lamrouex, MDOT Bureau of Aeronautics and Freight Services, 2700 Port Lansing Road, Lansing, MI 48906. The Draft EA can be reviewed at the following locations:

(a) Ann Arbor City Library, 343 S. Fifth Ave., Ann Arbor, MI 48104
(b) Pittsfield Township Hall, 6201 W. Michigan Ave., Ann Arbor, MI 48108
(c) Ann Arbor Municipal Airport, 801 Airport Dr., Ann Arbor, MI 48103
(d) Ann Arbor City Hall, 100 N. Fifth Ave., Ann Arbor, MI 48104
(e) MDOT BAFS, 2700 Port Lansing Road, Lansing MI 48906

Copies of the Draft EA are available by contacting Molly Lamrouex, MDOT Bureau of Aeronautics and Freight Services, 2700 Port Lansing Road, Lansing, MI 48906 or by phone at 517–335–9866. The Draft EA is also available at *http://www.a2gov.org/government/publicservices/fleetandfacility/Airport/Pages/default.aspx* A public hearing to provide information on the draft EA and accept comments from the public will be held from 4 to 7 p.m. on Wednesday, March 31, 2010 at the Cobblestone Farm Barn, 2781 Packard Rd., Ann Arbor, MI 48108.

SUPPLEMENTARY INFORMATION: The EA includes analysis used to evaluate the potential environmental impacts in the study area. Upon publication of the Draft EA and a Final EA, MDOT will be coordinating with federal, state and local agencies, as well as the public, to obtain comments and suggestions regarding the EA for the proposed project. The Draft EA assesses impacts and reasonable alternatives including a no action alternative pursuant to NEPA; FAA Order 1050.1, Policies and Procedures for Considering Environmental Impacts; FAA Order 5050.4B, National Environmental Policy Act (NEPA) Implementing Instructions for Airport Actions; and the President's Council on Environmental Quality (CEQ) Regulations implementing the provisions of NEPA, and other appropriate Agency guidance.

Joe Hebert,

Acting Manager, Detroit Airports District Office, Great Lakes Region.

[FR Doc. 2010–5521 Filed 3–18–10; 8:45 am]

BILLING CODE 4910–13–P

DEPARTMENT OF TRANSPORTATION

Federal Transit Administration

Notice of Limitation on Claims Against Proposed Public Transportation Projects

AGENCY: Federal Transit Administration (FTA), DOT.

ACTION: Notice of Limitation on Claims.

SUMMARY: This notice announces final environmental actions taken by the Federal Transit Administration (FTA) for the following projects: (1) Jacksonville Transit Authority, Rapid Transit System Phase One, Jacksonville, FL; (2) Salem-Keizer Transit, Keizer Transit Center Project, Salem, OR; (3) Massachusetts Bay Transportation Authority, Installation of Elevators at Park Street Station Project, Boston, MA; (4) Erie Metropolitan Transit Authority, Expansion of the 14th Street Bus Facility, Erie, PA; and (5) Metropolitan Council, Central Corridor Light Rail Transit Project—Construction of Three Infill Stations, St. Paul, MN. The purpose of this notice is to announce publicly the environmental decisions by FTA on the subject projects and to activate the limitation on any claims that may challenge these final environmental actions.

DATES: By this notice, FTA is advising the public of final agency actions subject to Section 139(l) of Title 23, United States Code (U.S.C.). A claim seeking judicial review of the FTA actions announced herein for the listed public transportation projects will be barred unless the claim is filed on or before September 14, 2010.

FOR FURTHER INFORMATION CONTACT: Antoinette Quagliata, Environmental Protection Specialist, Office of Planning and Environment, 202–366–4265, or Christopher Van Wyk, Attorney-Advisor, Office of Chief Counsel, 202–366–1733. FTA is located at 1200 New Jersey Avenue, SE., Washington, DC 20590. Office hours are from 9 a.m. to 5:30 p.m., EST, Monday through Friday, except Federal holidays.

SUPPLEMENTARY INFORMATION: Notice is hereby given that FTA has taken final agency actions by issuing certain approvals for the public transportation projects listed below. The actions on these projects, as well as the laws under which such actions were taken, are described in the documentation issued in connection with each project to comply with the National Environmental Policy Act (NEPA) and in other documents in the FTA administrative record for the project. Interested parties may contact either the project sponsor or the relevant FTA Regional Office for more information on these projects. Contact information for FTA's Regional Offices may be found at *http://www.fta.dot.gov.*

This notice applies to all FTA decisions on the listed projects as of the issuance date of this notice and all laws under which such actions were taken, including, but not limited to, NEPA [42 U.S.C. 4321–4375], Section 4(f) of the Department of Transportation Act of 1966 [49 U.S.C. 303], Section 106 of the National Historic Preservation Act [16 U.S.C. 470f], and the Clean Air Act [42 U.S.C. 7401–7671q]. This notice does not, however, alter or extend the limitation period of 180 days for challenges of project decisions subject to previous notices published in the **Federal Register**. For example, this notice does not extend the limitation on claims announced in the **Federal Register** on September 2, 2009 (74 FR 169) for the original Record of Decision (ROD) issued for the Central Corridor Light Rail Transit Project.

The projects and actions that are the subject of this notice are:

1. *Project name and location:* Jacksonville Rapid Transit System Phase One—Downtown Transit Enhancements, Jacksonville, FL. *Project sponsor:* Jacksonville Transit Authority. *Project description:* The project will construct a Bus Rapid Transit system in Jacksonville, Florida. This project is a part of an overall strategy to bring high-capacity public transit to downtown Jacksonville. The 5.6 mile system will include: Restructured bus routes, 2.84 miles of dedicated bus lanes, 15 station-stop enhancements, a traffic signal priority system, and a real-time traveler information network. *Final agency actions:* Section 106 finding of no adverse effect; project-level air quality conformity determination; no use of Section 4(f) properties; and a Finding of No Significant Impact (FONSI) signed February 11, 2010. *Supporting documentation:* Supplemental Environmental Assessment dated November 2009 and Environmental Assessment dated September 2008.

2. *Project name and location:* Keizer Transit Center Project, Salem, OR. *Project sponsor:* Salem-Keizer Transit. *Project description:* The project will construct a transit hub for the medium-sized community of Salem, Oregon, located 40 miles south of Portland. The proposed Keizer Transit Center will accommodate transfers between bus routes, have a 70-space park-and-ride lot, a passenger plaza, a kiss-and-ride lot, a transit information kiosk, and bicycle storage units. *Final agency actions:* Section 106 finding of no adverse effect; project-level air quality conformity determination; no use of Section 4(f) properties; and a Finding of No Significant Impact (FONSI) signed February 4, 2010. *Supporting documentation:* Environmental Assessment dated December 2009.

3. *Project name and location:* Installation of Elevators at Park Street Station, Boston, MA. *Project sponsor:* Massachusetts Bay Transportation Authority. *Project description:* The project will modernize elevators at the Park Street Station of the Massachusetts Bay Transportation Authority. Park Street is an intersection point for both the Green and Red subway lines. The station has a unique historic heritage, originally built in 1897, as one of America's first street-level subway systems. The current travel path between the Green and Red Lines requires three elevator transfers and an approximate 0.10 mile walk. This path is unduly long and can pose a challenge for persons with limited mobility or low physical stamina. The purpose of the project is to provide a shorter elevator-accessible path between the Green Line westbound platform and Red Line center platform. *Final agency actions:* Section 106 finding of no adverse effect; project-level air quality conformity determination; Section 4(f) de minimis impact determination; and a Finding of No Significant Impact (FONSI) signed December 29, 2009. *Supporting documentation:* Environmental Assessment dated August 2009.

4. *Project name and location:* Expansion of the 14th Street Bus Facility, Erie, PA. *Project sponsor:* Erie Metropolitan Transit Authority. *Project description:* The project involves the expansion of a bus maintenance and storage facility in Erie, Pennsylvania. Located on the western coast of Pennsylvania, the city of Erie is 120 miles north of Pittsburg. The proposed 9-acre site will house bus maintenance, storage, fueling, and washing facilities. Site plans also include provisions for additional parking and administrative office space. In total, the project will centralize operations from nine under-utilized buildings into the new facility. *Final agency actions:* Section 106 finding of no adverse effect; project-level air quality conformity

Re: Comments by The Charter Township of Pittsfield on the Environmental Assessment for Ann Arbor Municipal Airport

Dear Ms. Lamrouex:

The following comments are submitted on behalf of The Charter Township of Pittsfield on the February 2010 Environmental Assessment for Ann Arbor Municipal Airport ("EA").

I. THE PROJECT'S STATED PURPOSE AND NEED IS UNSUPPORTED BY THE EVIDENCE.

An EA must include a discussion of the purpose and need for the proposed action which must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." [40 C.F.R. § 1502.13]. In addressing the Purpose and Need section of an EA, FAA Order 1050.1E provides that: "This discussion identifies the problem facing the proponent (that is, the need for an action), the purpose of the action (that is, the proposed solution to the problem), and the proposed timeframe for implementing the action." FAA Order 1050.1E, ¶ 405c. The EA accomplishes none of these goals.

A. The EA Supports Neither the Problem it Aims to Solve Nor its Purported Solution.

First, the EA defines the *purpose* of the Project[1] as "to provide facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport." [EA, p. 2-4]. The EA defines "critical aircraft" as "the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport," *Id*., and states that a 2009 MDOT Airport User Survey "has confirmed that the critical aircraft classification for ARB is 'B-II Small Aircraft.'" *Id*.

To effectuate the stated purpose, the EA purports to support the construction of a runway extension from 3,505 feet to 4,300 feet. However, the extant evidence is clear that no "B-II Small Aircraft" require a 4,300 foot long runway. All B-II Small Aircraft are capable of operating on the existing 3,505 feet long runway without weight restriction. *See*, attached Williams Aviation Consultants Report [incorporated herein by reference]. In fact, the representative B-II Small Aircraft cited in the EA, the Beechcraft King Air 200, requires only 2,579 feet of runway to take-off fully loaded, and 2,845 feet to land. *See*, http://www.hawkerbeechcraft.com/beechcraft/ king_airb200gt/specifications.aspx. Thus, the statement that "[d]evelopment of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small Aircraft to operate at their optimum capabilities (without weight restrictions)" [p. 2-4], although true, is misleading. There is no need to extend Runway 6/24 to allow B-II aircraft to operate at ARB. They can operate on a 3,505 foot runway without weight restrictions. Therefore, the statement that interstate commerce would be negatively impacted by B-II Small weight restrictions does not state a valid need, and the purported purpose of "provid[ing] facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport" is an unnecessary solution to a nonexistent problem.

B. The EA Incorrectly Relies on ***Total*** Annual Operations to Support the Proposed Runway Extension.

The EA states, "[t]he critical aircraft, or grouping of aircraft are generally the largest, most demanding types that conduct at least 500 operations per year at the airport" [EA, p. 2-7], and concludes that the proper Airport Reference Code ("ARC") for ARB is "B-II Small", based on a total of "750 actual annual operations by B-II category critical aircraft from survey data year

---

[1] The proposed improvements described at page 2-1 of the EA are referred to herein as the "Project."

2007." [EA, p. 2-9]. However, the EA's use of "annual operations" differs markedly from the FAA criteria for selecting runway lengths and widths set forth in FAA Order 5090.3C:

> 3-4. AIRPORT DIMENSIONAL STANDARDS
>
> Airport dimensional standards (such as runway length and width, separation standards, surface gradients, etc.) should be selected which are appropriate for the critical aircraft that will make substantial use of the airport in the planning period. Substantial use means either 500 or more annual ***itinerant*** operations, or scheduled commercial service. FAA Order 5090.3C, p. 21 (emphasis added).

(FAA Order 5090.3C does not state that critical aircraft must be the "largest.")

The FAA divides General Aviation operations into two categories, "local" and "itinerant." Itinerant operations are defined as "an operation performed by an aircraft, either IFR, SVFR, or VFR, that lands at an airport, arriving from outside the airport area, or departs an airport and leaves the airport area." [U.S. DOT JO 7210.695, p. 5]. Local operations are defined as "those operations performed by aircraft that remain in the local traffic pattern, execute simulated instrument approaches or low passes at the airport, and the operations to or from the airport and a designated practice area within a 20-mile radius of the tower." *Id*.

The EA, without reference to this distinction, relies on "annual operations" and "total annual operations" not "itinerant operations," *see,* EA, Table 2-1, p. 2-10. Separating itinerant and local operations at ARB would result in a dramatic reduction in the number of annual critical aircraft operations at the airport. For example, data from the website City-Data.com shows that there were 29,322 itinerant operations and 43,573 local operations at ARB in 2007, the year used by MDOT in the EA. *See*, http://www.city-data.com/airports/Ann-Arbor-Michigan.html. In that itinerant operations account for approximately 40% of the total operations at ARB, itinerant B-II operations for 2007 would be in the neighborhood of 300 operations per year [40% of 750 total operations], substantially below the FAA's threshold of 500 annual operations to constitute "substantial use." Moreover, the Airport User Survey shows only 293 annual B-II Small operations at ARB in 2007. [EA Appendix A-1, p. 7]. Thus, the FAA Order 5090.3C airport dimensional standards for B-II small aircraft do not apply.

C. Shifting Runway 6/24 150 Feet to the Southwest Will Not Achieve an Additional Margin of Safety.

The EA states as part of its purpose to "[e]nhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road." [EA, p. 2-5]. Operational safety in low visibility conditions will not be enhanced by providing a clear 34:1 approach surface to Runway 24. The EA is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel. [EA, p. 2-5]. However, in the next paragraph the EA states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles." [EA, p. 2-5]. This statement lacks support in either the Instrument Approach Procedure (IAP) design or Terminal Instrument Procedures ("TERPS") Obstruction Standards.

Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP, and are defined as "Obstacle Identification Surfaces" which do not establish obstacle clearance safety margins, but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety," as stated in the EA, does not apply in the case of these two surfaces. Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions, and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the FAA to accommodate all existing obstructions. Thus, shifting the runway 150' southwest would not enhance safety. Assuming that the EA is correct in the assertion that shifting the Runway 24 threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement, but would result only in a reduction in the required approach visibility minimums. [*See*, attached Williams Aviation Consultants Report]

II. THE EA DOES NOT CONSIDER ALL REASONABLE ALTERNATIVES.

The National Environmental Policy Act ("NEPA") [42 U.S.C. §§ 4321 *et seq.*] requires that federal agencies examine all reasonable alternatives in preparing environmental documents. [42 U.S.C. § 4332(c)(iii)]. An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action is intended to address. The Council on Environmental Quality ("CEQ") Regulations ("NEPA Regulations"), which implement NEPA, require that Federal agencies "[u]se the NEPA process to identify and assess the reasonable alternatives to the proposed actions that will avoid or minimize adverse effects of these actions upon the quality of the human environment" 40 C.F.R. § 1500.2(e), and that "agencies shall . . . (a) Rigorously explore and objectively evaluate all reasonable alternatives . . ." 40 C.F.R. § 1502.14(a). The EA fails to explore all reasonable alternatives to the Preferred Alternative selected.

The EA [p. 2-5] lists five objectives of the proposed project:

- Enhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions.
- Enhance operational safety by improving the FAA ATCT line-of-sight issues.
- Enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road.
- Reduce the occurrence of runway overrun incidents by small category A-I aircraft (local objective).
- Relocate and potentially upgrade the Runway 24 Approach Light System.

As shown in Section I above, enhancing interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions is not a valid need. Further, lengthening Runway 6/24 is not necessary to achieve the remaining four objectives. Those objectives could be met by simply shifting Runway 6/24 150 feet to the southwest, *i.e.*, removing 150 feet from the approach end of Runway 24 and adding 150 feet to the departure end of Runway 24. Runway length would remain 3,505 feet.

Section 2.2.1 of the EA states that a 150-foot shift of the Runway 24 threshold to the west would (1) enhance the safety of ground operations by taxiing aircraft; (2) enhance operational safety, and possibly prevent runway incursions, by expanding the view of the hold area and parallel taxiway to ATCT personnel; (3) allow for a clear 34:1 approach surface to the east end of the runway, providing an added margin of safety between approaching aircraft and ground-based obstacles, which is particularly beneficial when aircraft are operating in low-visibility conditions; and (4) include relocation and replacement of the existing runway approach light system with newer Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF). [EA, pp. 2-5, 2-6]. Shifting Runway 6/24 150 feet to the southwest without lengthening the runway would also accommodate future widening of State Road. Nevertheless, this reasonable alternative was not considered in the EA.

An Environmental Assessment "shall include brief discussions of . . . alternatives . . ." 40 C.F.R. § 1508.9(b).[2] Absent an analysis of an alternative based on a 150-foot southwesterly shift of the runway, without lengthening the runway, the EA is inadequate.

III. THE EA FAILS TO ADEQUATELY ANALYZE OR DISCLOSE THE PROJECT'S AIR QUALITY IMPACTS WHERE IT FAILS TO ADDRESS OR DETERMINE THE PROJECT'S CLEAN AIR ACT CONFORMITY.

Section 7506 of the Federal Clean Air Act [42 U.S.C. §§ 7401 *et seq*.] mandates that "[n]o department, agency, or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to [a State Implementation Plan] after it has been approved or promulgated under [42 U.S.C. § 7410]." The Environmental Protection Agency (EPA) has promulgated regulations implementing Section 7506 (the "Conformity Provision") in 40 C.F.R. §§ 93.150 *et seq*. ("General Conformity Rule"). The General Conformity Rule requires, in part, that Federal agencies first determine if a project is either exempt from conformity analysis or presumed to conform. If it is neither, the agency must conduct a conformity applicability analysis to determine if a full conformity determination is required. *See*, *Air Quality Procedures for Civilian Airports and Air Force Bases*, p. 13.

The project area, *i.e.*, Washtenaw County, is in attainment for five of the seven criteria pollutants [p. 4-17], and marginal nonattainment for Ozone [p. C-3].[3] The area is designated as in nonattainment for $PM_{2.5}$. [EA, p. C-4]. Therefore, one of the following must apply: (1) the Project is exempt from conformity; or (2) the Project is presumed to conform; or (3) the agency must conduct a conformity applicability analysis to determine if a conformity determination for $PM_{2.5}$ is required. The EA does not indicate that any of the required actions was performed.

---

2 Courts have consistently held that the "existence of reasonable but unexamined alternatives renders an EIS inadequate." *See, e.g., Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998).

3 The original six criteria pollutants are Ozone (O3), Particulate Matter (PM_{10}), Carbon Monoxide (CO), Nitrogen Oxides (NO2), Sulfur Dioxide (SO2) and Lead (Pb). FAA Order 1050.1E ("Environmental Impacts; Policies and Procedures"), p. A-3, ¶ 2.1b, includes both PM_{10} and $PM_{2.5}$ under the category Particulate Matter. On April 5, 2010 the EPA published Revisions to the General Conformity Regulations Final Rule [75 Fed. Reg. 17254-279 (2010)] which, among other things, added $PM_{2.5}$ to the list of criteria pollutants in 40 C.F.R. § 93.153(b).

As a threshold matter, the EA is internally inconsistent with regard to whether the Project is exempt or presumed to conform. At page C-4, the EA states unequivocally that "[f]or this analysis it will be assumed that the project is neither exempt nor presumed to conform." [Emphasis added.] However, at page C-5 the EA states ". . . a conformity determination is not required and the proposed project is presumed to conform to the state implementation plan." [Emphasis added.] Under either scenario, however, the EA is deficient and fails to meet the "public disclosure" requirement under the National Environmental Policy Act ("NEPA"), 42 U.S.C. §§ 4321 *et seq*.

A. The EA Fails to Establish That the Project Is Exempt.

A federal agency has two options to determine that a project is exempt from conformity analysis: (1) if the project is included in the list of exempt actions listed in § 93.153(c)(2); or (2) if the project's total of direct and indirect emissions are below the emissions levels specified in § 95.153(b) of the Conformity Regulations ("*de minimis*"). § 93.153(c)(1).

The first option does not apply here because runway and taxiway extension projects such as the one described in the EA [p. 2-1] are not included in the exempt actions listed in § 93.153(c)(2). Nor does the EA establish that the Project can be considered exempt as *de minimis* under 40 C.F.R. § 93.153(c)(1). The EA instead relies on a 1996 MDOT Bureau of Aeronautics Air Quality Study of seven general aviation airports (which notably do not include ARB) for the conclusion that "typical GA airports generate a low level of pollutants." [EA, p. 4-17]. From that nonspecific conclusion, the EA further generalizes to the assertion that, because ARB is comparable in size and activity to the seven airports studied, it can be assumed that emissions resulting from the Project will not exceed the conformity threshold levels and, on that basis, concludes that a conformity analysis is not required.

This assumption is fatally flawed, however, for at least two reasons: (1) the EA does not quantify $PM_{2.5}$ emissions from flight operations at ARB at all, relying exclusively on the 1996 Study; and (2) because there is no quantification, there is also no comparison with the explicit *de minimis* thresholds established in 40 C.F.R. § 93.153(c)(1). It is correct that the original version of 40 C.F.R. § 93.153(c)(1) did not establish explicit thresholds for $PM_{2.5}$, as distinguished from PM_{10}. However, the newly implemented revised General Conformity Rule does establish that distinction, and now serves as the template for the air quality analysis required in the EA. Moreover, FAA Order 1050.1E, Appendix A, p. A3, § 2.16 includes both PM_{10} and $PM_{2.5}$ in "particulate matter."

B. The EA Fails to Establish That the Project Is Presumed to Conform.

The second option, the presumption of conformity does not apply here either. In July, 2007, the FAA published a "Federal Presumed to Conform Actions Under General Conformity Final Notice" [72 Fed.Reg. 41,565-580 (July 2007)] in which the FAA listed fifteen Airport Project categories which the FAA presumes to conform to applicable SIPs. The runway and taxiway extension project described in the EA does not fall within any of those presumed to conform categories. Therefore, the FAA cannot rely on the Presumed to Conform Final Notice to presume that the Project is in conformity.

C. The EA Fails to Establish the Project's Conformity Status.

Finally, even if, for argument's sake, the study of airports other than ARB were adequate for air quality analysis of ARB in the EA (which it is not), the 1996 Study would be an inadequate substitute for the required analysis. 40 C.F.R. § 93.159 requires that analyses under the General Conformity Rule be based on, among other things: (1) "the latest planning assumptions," § 93.159(a); and (2) "the latest and most accurate emissions estimation techniques available," § 93.159(b). The 1996, 14-year old, Study patently fails to fall within either, let alone both, of these parameters.

In summary, the EA fails to establish the existence of any of the necessary components of the required finding of conformity for a Federal project, and, thus, is inadequate under both NEPA and the Clean Air Act.

IV. THE EA FAILS TO ACCOUNT FOR WELLS ON AIRPORT PROPERTY.

While Section 4.5.2 of the EA purports to address "Geology, Groundwater, and Soils" affected by the Project, it understates the significance of the fact that water resources are a principal use of the grounds where the airport is located.

"If there is the potential for contamination of an aquifer designated by the [EPA] as a sole or principal drinking water resource for the area, the responsible FAA official needs to consult with the EPA regional office, as required by section 1424(e) of the Safe Drinking Water Act, as amended." FAA Order 1050.1E, pp. A-74, 75, ¶ 17.1c. "When the thresholds indicate that the potential exists for significant water quality impacts, additional analysis in consultation with State or Federal agencies responsible for protecting water quality will be necessary. *Id.*, pp. A-75, A-76, ¶ 17.4a. "If the EA and early consultation [with the EPA] show that there is a potential for exceeding water quality standards [or] identify water quality problems that cannot be avoided or mitigated . . . an EIS may be required. *Id.*, pp. A-75, ¶ 17.3.

There are two issues raised by the Project that require further examination in the EA. First, there is the issue of contamination from the Airport. The Airport is the location of a porous sand/gravel formation that yields a large amount of water for pumping Historically, the land where the Airport is located was originally acquired by the City of Ann Arbor for water rights in 1929. Until recently, 15% of Ann Arbor's water supply came from the three wells located on Airport property. Water Quality Report, 2008, City of Ann Arbor, p. 2 (available at http://www.a2gov.org/government/publicservices/water_treatment/documents/ccr.pdf). Due to the importance of the water supply at ARB, the EA needs to have more than a few passing words ("Based on coordination with the City of Ann Arbor, the proposed runway extension would not impact the water supply wells or the new water supply line (Bahl, 2009)"). [EA, p. 4-20].

Second, paving the area for a runway, roads, *etc.* increases the impervious area on the aquifer. This in turn reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer that it vital to the City of Ann Arbor. Further environmental review should provide detailed analyses of the impact of this increase in impervious surface, as well as the possibility of contamination, currently unexplored in the EA.

V. THE EA FAILS TO ANALYZE THE PRESENCE OF HAZARDOUS WILDLIFE NEAR THE AIRPORT AND FAILS TO PRESENT ANY MANDATORY MITIGATION MEASURES.

FAA Advisory Circular 150/5200-33B ["Hazardous Wildlife Attractants on or Near Airports"] contains standards for land uses that have the potential to attract hazardous wildlife on or near public-use airports. The standards are applicable to airport development projects, including airport construction, expansion and renovation. Airports that have received Federal grant-in-aid assistance must use these standards. [*See,* AC 150/5200-33B, p. ii]. The FAA recommends separation distances of 5,000 feet at airports that do not sell Jet-A fuel, and 10,000 feet at airports that sell Jet-A fuel for hazardous wildlife attractants. [AC 150/5200-33B, p.1]. ARB sells Jet-A fuel.

The FAA also "recommends a distance of 5 statute miles between the farthest edge of the airport's AOA [Air Operations Area] and the hazardous wildlife attractant if the attractant could cause hazardous wildlife movement into or across the approach or departure airspace." [AC 150/5200-33B, p. 1]. Finally, AC 150/5200-33B provides that "[a]irport operators should identify hazardous wildlife attractants and any associated wildlife hazards during any planning process for new airport development projects" [p. 17] and "[t]he FAA will not approve the placement of airport development projects pertaining to aircraft movement in the vicinity of hazardous wildlife attractants without appropriate mitigating measures." [pp. 17-18].

The FAA ranks geese as number three [3] in a list of the relative hazard to aircraft for 25 species groups. [AC 150/5200-33B, Table 1, p. iii]. However, the EA does not disclose that the area surrounding the airport is a prime habitat for large numbers of Canada Geese. EA Appendix F lists 38 species of birds that have either been observed, or for which there has been confirmed or probable breeding in Airport fields during 2006 through 2008. The list does not include Canada Geese. Canada Geese populate waterways on a golf course, in business parks and in neighboring wetlands located west and southwest of the Airport, well within the separation distances prescribed by the FAA.

The preferred alternative (Build Alternative 3) would extend Runway 6/24 950 feet to the southwest. The extension would allow aircraft landing on Runway 6 and departing on Runway 24 to overfly areas populated by Canada Geese at altitudes of less than 100 feet. The EA does not consider this hazardous condition. Even though they are not designated as "special concern", "threatened" or "endangered," the presence of Canada Geese in the Airport area poses a hazard to aircraft operational safety, and should be identified and analyzed in the EA, along with proper mitigation measures.

VI. <u>THE EA DOES NOT ACKNOWLEDGE OR ANALYZE THE PROJECT'S MANIFEST GROWTH-INDUCING IMPACTS</u>.

A Federal agency is required to evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project [40 C.F.R., § 1508.8(b)] and increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). "The growth-inducing effects of [a] project appear to be its raison d'etre." *Id*. The EA ignores this requirement, even though the Project is virtually defined by its growth-inducing impacts. Despite the fact that the EA assumes that the "percent of night and jet operations would remain constant between the existing condition and the future years" [EA, p. 4-2], there is substantial evidence to indicate that the Project will cause a large increase in both types of operations.

As indicated above, there are no weight restrictions that must be lifted to allow the EA's "critical aircraft" to operate at ARB without weight restrictions. The "load restrictions" referenced on page 2-12 refer not to category B-II aircraft, but to higher category aircraft (jets in the C-I and C-II categories) which must currently operate at reduced weights in order to use the 3,505-foot runway. (Required takeoff length is the primary restrictor.) Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, all of which discourage these aircraft from conducting operations at ARB.

For example, a Cessna Citation II (Category B-II) requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and can operate at unrestricted weight from the existing 3,505 foot runway. A Lear 35 (Category C-I), on the other hand, requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,300 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be less than is currently required. Therefore, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Citation jet, which the EA states is a "critical aircraft."

The longer runway will facilitate the loading of additional passengers and baggage on high performance jet aircraft. Also, the ability to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. If the runway is lengthened to 4,300 feet, it is reasonably foreseeable that ARB will become much more attractive to operators of higher performance jet aircraft, such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II), who could then operate at ARB instead of driving to and from Willow Run Airport.

Contrary to the unsupported assertions in the EA [EA, p. 42; Appendix B-1, p. B-4], it is reasonably foreseeable that the fleet mix will change in favor of a higher percentage of jet operations, as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft account for a high percentage of ARB operations. B-II aircraft account for a low percentage of ARB operations.

It is, therefore, reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer haul business jets often occur in the evening hours due to the longer time duration of their trips. Since one of the stated purposes of the EA is to increase interstate commerce, this is not merely an indirect, but also a direct effect, the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Thus, the evidence is clear that the Project will cause an increase in both jet *and* night operations. It is also reasonably foreseeable that these added high-performance jet aircraft operations and night operations will be accompanied by significant noise and air quality impacts. Nevertheless, the EA fails to acknowledge, let alone analyze, these reasonably foreseeable impacts caused by expansion of Airport physical facilities and operational profile and, thus, is inadequate.

VII. NOISE MODELING FOR THE PROJECT FAILED TO INCLUDE INCREASED JET AIRCRAFT AND NIGHTTIME OPERATIONS IN DEVELOPING NOISE CONTOURS.

The FAA's Integrated Noise Model ("INM") was used to model annual operations for the 2009 existing condition, *i.e.*, April 2008 through March 2009 [EA Appendix B-1, p. B-4] and develop 65, 70 and 75 DNL noise contours for the Project. [EA, p. 4-3]. The EA states that "[t]he existing 65 DNL contour does not extend beyond airport property." [EA, p. 4-3]. During the time modeled, jet operations accounted for approximately 2 percent of total operations at ARB, and nighttime operations accounted for 4.2 percent of total operations. [EA, p. 4-2]. The EA states: (1) "[t]he percent of night and jet operations would remain constant between the existing condition and the future years"; (2) "fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives would remain static" [EA, p. 4-2; Appendix B-1, p. B-4]; and "[t]he ARB 2014 proposed project alternative DNL 65 dBA noise contour does not extend beyond airport property." [EA, p. B-6].

However, as shown in Section VI above, the Project will likely facilitate an increased number of night operations, and a change in fleet mix, which will include higher performance jet aircraft. DNL calculations depend on, among other things, forecast numbers of operations, operational fleet mix and times of operation (day verses night). [EA, Appendix B-2, p. B-16]. However, the EA fails to model or assess future increased night operations and fleet mix changes resulting from the Project.

The FAA is required to use INM to produce, among other things: (1) noise contours at the DNL 75 dB, DNL 70 dB and DNL 65 dB levels; (2) analysis within the proposed alternative DNL 65 dB contour to identify noise sensitive areas where noise will increase by DNL 1.5 dB[4]; and (3) analysis within the ***DNL 60-65 dB contours*** to identify noise sensitive areas where noise will increase by DNL 3dB, ***if*** DNL 1.5 dB increases as documented within the DNL 65 dB contour. [FAA Order 1050.1E, Appendix A, p. A-62, ¶ 14.4d].

As the noise modeling failed to take into account the foreseeable increases in nighttime and jet aircraft operations at ARB, the questions of whether the future DNL 65 dB contour will be increased, and to what extent, and whether increased noise levels within the DNL 65 dB contour would necessitate designation of a DNL 60 dB contour remain unanswered.

---

4 A significant noise impact would occur if analysis shows that the proposed action will cause noise sensitive areas to experience an increase in noise of DNL 1.5 dB or more at or above DNL 65 dB noise exposure when compared to the no action alternative for the same timeframe." [FAA Order 1050.1E, Appendix A, P. A-61, ¶ 14.3]

VIII. THE EA FAILS TO CONSIDER THE POLITICAL JURISDICTIONS AFFECTED BY THE PROJECT.

FAA Order 5050.4B, paragraph 706 provides a format for integrating the NEPA process with special purpose laws outside the scope of NEPA in preparing environmental assessments. Paragraph 706.e.(4) requires that an environmental assessment address "[p]olitical jurisdiction(s) the proposed action would affect." The EA fails to do that. The EA does not disclose that Pittsfield Township, the political jurisdiction in which the Project is located, and neighboring Lodi Township have both passed resolutions opposing the Project. The EA also fails to identify or analyze the effect that environmental impacts, which are certain to result from the Project (*e.g.*, noise, air quality, safety, economic impacts, *etc.*), will have on those political jurisdictions.

IX. CONCLUSION.

Given the Project's many potential significant environmental impacts that have not been identified or analyzed in the EA, a full Environmental Impact Statement (EIS) is required prior to approval and implementation of the Project. "No matter how thorough, an EA can never substitute for preparation of an EIS, if the proposed action could significantly affect the environment." *Anderson v. Evans*, 371 F.3d 475, 494 (9th Cir. 2004).

Sincerely,

CHEVALIER, ALLEN & LICHMAN, LLP

BC Hart

for Barbara E. Lichman, Ph.D.

Attachment (1)

Williams Aviation Consultants, Inc. was retained by the law firm of Chevalier, Allen & Lichman, LLP to review and comment on Chapters 1 and 2, and Appendices A and B of the DRAFT Ann Arbor Municipal Airport Environmental Assessment (DEA), February, 2010. The following are our comments on the DEA.

A. Accommodating the Critical Aircraft at Ann Arbor Municipal Airport (ARB)

As stated in paragraph 2.2.7, "*The proposed shift and extension of primary Runway 6/24 at ARB would provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility.* (Emphasis added)

In particular, the proposed project would provide the following benefits:

- *Enhance business aviation and interstate commerce by providing sufficient runway length to allow the majority of category B-II Small critical aircraft that currently use ARB to operate without load restrictions (i.e. reduction in passengers, cargo, and fuel associated with aircraft range).* (Emphasis added)

According to paragraph 2.2, Purpose and Need, "The purpose of the proposed improvements at ARB is to provide facilities that more effectively and efficiently *accommodate the critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport. (Emphasis added)

The critical aircraft is defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the critical aircraft weigh less than 60,000 lbs, a classification of aircraft is used rather than a specific individual aircraft model. A recent Airport User Survey has confirmed that the critical aircraft classification for ARB is "*B-II Small Aircraft.*" (Emphasis added)

Also stated under "Purpose and Need" "*Development of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions).* (Emphasis added)

WAC Comment: There are no aircraft in the B-II Small aircraft classification that require a runway length of 4,300 feet to conduct normal operations. All B-II Small Aircraft are capable of operating out of the current runway (3,505 feet long) without the need to reduce weight by off-loading passengers, baggage or fuel.

Regarding the establishment of the critical aircraft, ARB lacks the required number of 500 annual operations by B-II Small Aircraft, so they have added larger aircraft such as B-II Large, Category C-I and C-II operations to meet the 500 classification requirement. It is the Category C-I and C-II aircraft which would benefit by the runway extension to 4,300 feet, not

those aircraft that fall within the definition of Category B-II Small Aircraft. The current runway length of 3,500 feet is sufficient to handle all Category B-II Small Aircraft.

B. Lengthening Runway 6/24 to 4,300 Feet: The Impact on Aircraft Load Restrictions and Fleet Mix

The "load restrictions" referenced above in paragraph 2.2.7 refer to the fact that the higher category aircraft (primarily jets in the C-I and C-II categories) must currently operate at reduced weights in order to operate out of the current 3,500 foot runway (required takeoff length is the primary restrictor). Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel; all of which discourage these aircraft from conducting operations out of ARB.

For example: A Cessna Citation II (Category B-II) requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day and may therefore operate unrestricted as to weight from the current 3,500 foot runway. A Lear 35 (Category C-I) requires 5,000 feet for takeoff at maximum certificated gross weight on the same standard day.

The Category B-II Citation II can conduct unrestricted operations from the current 3,500 foot runway. Whereas extending the runway to 4,300 feet would not facilitate unrestricted operations by the Category C–I, Lear 35, the required weight reduction would be less than is currently required. In this way, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Small Citation jet, or any other Category B-II Small aircraft.

All Category B-II Small aircraft, i.e. the ARB critical design aircraft, are currently accommodated on the existing 3,500 foot runway. Contrary to what is stated in the DEA, lengthening the runway to 4,300 feet WOULD NOT "provide a runway configuration that more effectively accommodates the <u>critical aircraft</u> that presently use the facility."

If the runway is lengthened to 4,300 feet, other jets such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II) may be able to operate out of ARB with minor reductions in takeoff weight. This will impact the community as it could reasonably be expected that the longer runway will attract more of the larger, higher performance jet aircraft to the airport.

These added high performance jet aircraft operations will be accompanied by noise and air quality impacts. Many of these operations will take place at night, thereby negatively affecting the general quiet of the surrounding community.

C. **Shifting Runway 6/24 150 Feet to the West While Maintaining the Current Runway Length of 3,500 Feet: The Impact on Load Restrictions, Future Fleet Mix and Safety of Operations**

Load Restrictions

Maintaining the current runway length of 3,500 feet would mean that the Category C-1 and C-II aircraft would continue to suffer significant load restrictions. These load restrictions would thereby continue to serve as a deterrent to these aircraft operating out of ARB.

Future Fleet Mix

Maintaining the current runway length would serve to maintain the current fleet mix. Category B-II Small jet aircraft include lower powered models such as the smaller versions of the Cessna Citation (Category B-I/II) and the Mitsubishi Diamond jet (Category B-I). Higher powered jet aircraft such as the Lear 25 (Category C-I), Lear 35 (Category C-I), IAI Astra (Category C-I) and Cessna Citation III (Category C-II) may be generally discouraged from flying into Ann Arbor and would generally, with few exceptions choose to land at Detroit and drive the 40 miles to Ann Arbor.

Safety of Operations

2.2.1 Safety Enhancements:

In the first paragraph, the consultant is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel.

However, in the next paragraph the consultant states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles."

This statement betrays a lack of understanding by the consultant of Instrument Approach Procedure (IAP) design and TERPS Obstruction Standards. Regarding the 20:1 and the 34:1 surfaces; it is not either/or, but both/and. Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP and are defined as "Obstacle Identification Surfaces" which do not establish obstacle clearance safety margins but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety" as stated by the consultant does not apply in the case of these two surfaces.

Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the

FAA to accommodate all existing obstructions. In this respect, shifting the runway 150' to the west would not enhance safety.

Summary: Assuming that the consultant is correct in their assertion that shifting the threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement but would only result in a reduction in the required approach visibility minimums.

D. Appendix B Noise Analysis Report
B-1 Noise Impact Analysis
B.1.3 Data
Flight Operations

The consultant states "INM-modeled annual operations for the 2009 existing condition, consisting of operations from April 2008 through March 2009, totaled 61,969 operations, which is approximately 169 daily operations. Jet operations accounted for approximately 2 percent of the total operations. Nighttime operations accounted for 4.2 percent of the total operations."

2014 future condition aircraft operations were obtained from the 2008 FAA TAF for ARB. Modeled annual operations for the 2014 condition totaled 69,717 operations, or approximately 191 daily operations. *It is assumed that the percent of night and jet operations will remain constant between the existing condition and the future years. In addition, it is also assumed that the fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives will remain static.* The existing and future fleet mix with annual operations is shown in Table B-2." (Emphasis added)

The consultant wrongly assumes that the percent of night and jet operations will remain constant, and that the fleet mix will remain static if Runway 6/24 is lengthened to 4,300 feet.

The longer runway will make ARB much more attractive to larger and higher performance jet aircraft as the added runway length will facilitate the loading of additional passengers and baggage on to these aircraft. Also, being able to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. As ARB becomes more attractive to higher performance jet aircraft, these larger aircraft may then consider operations to/from ARB in lieu of landing at Detroit and driving to Ann Arbor.

As more high performance jet aircraft begin operations at ARB, the fleet mix will change in favor of a higher percentage of jet operations as compared to the current level of light single and multiengine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft currently reflect a high percentage of ARB operations. B-II Small aircraft (the critical design aircraft) reflect a low percentage of ARB operations. Recall that Category B-II Large and Category C aircraft had to be added to the currently operating Category B-II Small aircraft design group in order to meet the 500 operation requirement for establishing the critical aircraft and thereby justify the runway extension.

The number of night operations also has the strong potential to increase as the number of arrivals of the larger, longer haul business jets often occur in the evening hours due to the longer time duration of their trips. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Re: Comments by The Committee for Preserving Community Quality on the Environmental Assessment for Ann Arbor Municipal Airport

Dear Ms. Lamrouex:

The Committee for Preserving Community Quality, a community group representing approximately 400 residents of Pittsfield and Lodi Townships and the cities of Ann Arbor and Saline, is filing these comments to strenuously object to the February 2010 Environmental Assessment for Ann Arbor Municipal Airport ("EA"). We feel, as the evidence below conclusively documents, that the EA is seriously flawed and that the proposed project is both dangerous and cannot be justified.

I. THE PROJECT'S STATED PURPOSE AND NEED IS UNSUPPORTED BY THE EVIDENCE.

An EA must include a discussion of the purpose and need for the proposed action which must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." [40 C.F.R. § 1502.13]. In addressing the Purpose and Need section of an EA, FAA Order 1050.1E provides that: "This discussion identifies the problem facing the proponent (that is, the need for an action), the purpose of the action (that is, the proposed solution to the problem), and the proposed timeframe for implementing the action." FAA Order 1050.1E, ¶ 405c. The EA accomplishes none of these goals.

A. The EA Supports Neither the Problem it Aims to Solve Nor its Purported Solution.

First, the EA defines the *purpose* of the Project as "to provide facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport." [EA, p. 2-4]. The EA defines "critical aircraft" as "the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport," *Id.*, and states that a 2009 MDOT Airport User Survey "has confirmed that the critical aircraft classification for ARB is 'B-II Small Aircraft.'" *Id.* To effectuate the stated purpose, the EA purports to support the construction of a runway extension from 3,505 feet to 4,300 feet. However, the extant evidence is clear that no "B-II Small Aircraft" require a 4,300 foot long runway. All B-II Small Aircraft are capable of operating on the existing 3,505 feet long runway without weight restriction. *See*, attached Williams Aviation Consultants Report [incorporated herein by reference]. In fact, the representative B-II Small Aircraft cited in the EA, the Beechcraft King Air 200, requires only 2,579 feet of runway to take-off fully loaded, and 2,845 feet to land. *See*, http://www.hawkerbeechcraft.com/beechcraft/ king_airb200gt/specifications.aspx. Thus, the statement that "[d]evelopment of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small Aircraft to operate at their optimum capabilities (without weight restrictions)" [p. 2-4], although true, is misleading. There is no need to extend Runway 6/24 to allow B-II aircraft to operate at ARB. They can operate on a 3,505 foot runway without weight restrictions. Therefore, the statement that interstate commerce would be negatively impacted by B-II Small weight restrictions does not state a valid need, and the purported purpose of "provid[ing] facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport" is an unnecessary solution to a nonexistent problem.

B. The EA Incorrectly Relies on *Total* Annual Operations to Support the Proposed Runway Extension.

The EA states, "[t]he critical aircraft, or grouping of aircraft are generally the largest, most demanding types that conduct at least 500 operations per year at the airport" [EA, p. 2-7], and concludes that the proper Airport Reference Code ("ARC") for ARB is "B-II Small", based on a total of "750 actual annual operations by B-II category critical aircraft from survey data year 2007." [EA, p. 2-9]. However, the EA's use of "annual operations" differs markedly from the FAA criteria for selecting runway lengths and widths set forth in FAA Order 5090.3C:

3-4. AIRPORT DIMENSIONAL STANDARDS

> Airport dimensional standards (such as runway length and width, separation standards, surface gradients, etc.) should be selected which are appropriate for the critical aircraft that will make substantial use of the airport in the planning period. Substantial

> use means either 500 or more annual ***itinerant*** operations, or scheduled commercial service. FAA Order 5090.3C, p. 21 (emphasis added).

(FAA Order 5090.3C does not state that critical aircraft must be the "largest.")

The FAA divides General Aviation operations into two categories, "local" and "itinerant." Itinerant operations are defined as "an operation performed by an aircraft, either IFR, SVFR, or VFR, that lands at an airport, arriving from outside the airport area, or departs an airport and leaves the airport area." [U.S. DOT JO 7210.695, p. 5]. Local operations are defined as "those operations performed by aircraft that remain in the local traffic pattern, execute simulated instrument approaches or low passes at the airport, and the operations to or from the airport and a designated practice area within a 20-mile radius of the tower." *Id.*

The EA, without reference to this distinction, relies on "annual operations" and "total annual operations" not "itinerant operations," *see* EA, Table 2-1, p. 2-10. Separating itinerant and local operations at ARB would result in a dramatic reduction in the number of annual critical aircraft operations at the airport. For example, data from the website City-Data.com shows that there were 29,322 itinerant operations and 43,573 local operations at ARB in 2007, the year used by MDOT in the EA. *See*, http://www.city-data.com/airports/Ann-Arbor-Michigan.html. In that itinerant operations account for approximately 40% of the total operations at ARB, itinerant B-II operations for 2007 would be in the neighborhood of 300 operations per year [40% of 750 total operations], substantially below the FAA's threshold of 500 annual operations to constitute "substantial use." Moreover, the Airport User Survey shows only 293 annual B-II Small operations at ARB in 2007. [EA Appendix A-1, p. 7]. Thus, the FAA Order 5090.3C airport dimensional standards for B-II small aircraft do not apply.

Even if, for argument's sake, we were to accept the critical aircraft data reported in the Airport User Survey [EA Appendix A-1, p.7], a detailed analysis shows that a weighted average of 78 percent of those B-II aircraft operations took place within a 450-mile radius of ARB, according to MDOT's own data analysis (Exhibit 1). These represent areas that are within the flight range of ARB's current based fleet, according to the User Survey data, from the current-length runway. Thus, by another means of calculus, itinerant operations beyond the range of need are fewer than 200 and Purpose and Need fails.

Further, MDOT's choice of 2007 as a year of certification for critical aircraft was based on an arbitrary and capricious decision. The year 2007 represents the greatest number of ARB operations in the 5-year period 2004-2009 and was selected, according to the MDOT analyst involved, because "our thoughts were that the current recession could possibly have affected the 2008 operational levels in such a way that 2008 year records would not be a true indicator of a post-recession return to normal operations at the airport. . .." (Noel, 2009). Even the FAA suggests ARB will not return to such high operating levels as 2007 for the next 20 years [FAA Terminal Area Forecast, EA, p. 2-10.] Thus, MDOT was showing bias and affording Ann Arbor a huge advantage in not even evaluating operational data from any other year. Objectively, since its standard is the independent Flight Aware data base, MDOT should analyze critical aircraft operational data for the five years 2004-2009 and base its decision on an average of those years' operational data.

C. Shifting Runway 6/24 150 Feet to the Southwest Will Not Achieve an Additional Margin of Safety.

The EA states as part of its purpose to "[e]nhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road." [EA, p. 2-5]. Operational safety in low visibility conditions will not be enhanced by providing a clear 34:1 approach surface to Runway 24. The EA is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel. [EA, p. 2-5]. However, in the next paragraph the EA states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles." [EA, p. 2-5]. This statement lacks support in either the Instrument Approach Procedure (IAP) design or Terminal Instrument Procedures ("TERPS") Obstruction Standards.

Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP, and are defined as "Obstacle Identification Surfaces" which do not establish obstacle clearance safety margins, but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety" as stated in the EA does not apply in the case of these two surfaces. Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions, and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the FAA to accommodate all existing obstructions. Thus, shifting the runway 150' west would not enhance safety. Assuming that the EA is correct in the assertion that shifting the Runway 24 threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement, but would result only in a reduction in the required approach visibility minimums. [*See*, attached Williams Aviation Report]

D. EA Falsely Intends to Convey Rural Setting in Densely Populated Area

The EA intends to deceive readers as to the cosmopolitan location of the airport, utilizing Figure 2.1 [Page 2-2], for instance, which depicts unpaved Lohr and Textile Roads and vacant land and rock pits and gravel pits where developed communities of Pittsfield (Brian Hill, Lake Forest, Lake Forest Highlands, Lohr Lakes Village, St. James Woods, Silo Ridge, Stonebridge, and Waterways) and Lodi (Travis Pointe) Townships exist today, with more than 2,000 homes – making the area appear far more rural and not susceptible to the safety risks from added airport development that are actually posed.

II. THE EA DOES NOT CONSIDER ALL REASONABLE ALTERNATIVES.

The National Environmental Policy Act ("NEPA") [42 U.S.C. §§ 4321 *et seq.*] requires that federal agencies examine all reasonable alternatives in preparing environmental documents. [42 U.S.C. § 4332(c)(iii)]. An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action is intended to address. The Council on Environmental Quality ("CEQ") Regulations ("NEPA Regulations"), which implement NEPA, require that Federal agencies "[u]se the NEPA process to identify and assess the reasonable alternatives to the proposed actions that will avoid or minimize adverse effects of these actions upon the quality of the human environment" 40 C.F.R. § 1500.2(e), and that "agencies shall . . . (a) Rigorously explore and objectively evaluate all reasonable alternatives . . ." 40 C.F.R. § 1502.14(a). The EA fails to explore all reasonable alternatives to the Preferred Alternative selected.

The EA [p. 2-5] lists five objectives of the proposed project:

- Enhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions.
- Enhance operational safety by improving the FAA ATCT line-of-sight issues.
- Enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road.
- Reduce the occurrence of runway overrun incidents by small category A-I aircraft (local objective).
- Relocate and potentially upgrade the Runway 24 Approach Light System.

As shown in Section I above, enhancing interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions is not a valid need. Further, lengthening Runway 6/24 is not necessary to achieve the remaining four objectives. Those objectives could be met by simply shifting Runway 6/24 150 feet to the southwest, *i.e.*, removing 150 feet from the approach end of Runway 24 and adding 150 feet to the departure end of Runway 24. Runway length would remain 3,505 feet. Section 2.2.1 of the EA states that a 150-foot shift of the Runway 24 threshold to the west would (1) enhance the safety of ground operations by taxiing aircraft; (2) enhance operational safety, and possibly prevent runway incursions, by expanding the view of the hold area and parallel taxiway to ATCT personnel; (3) allow for a clear 34:1 approach surface to the east end of the runway, providing an added margin of safety between approaching aircraft and ground-based obstacles, which is particularly beneficial when aircraft are operating in low-visibility conditions; and (5) include relocation and replacement of the existing runway approach light system with newer Medium

Intensity Approach Lighting System with Sequenced Flashers (MALSF). [EA, pp. 2-5, 2-6]. Shifting Runway 6/24 150 feet to the Southwest without lengthening the runway would also accommodate future widening of State Road. Nevertheless, this "reasonable alternative" was not considered in the EA.

An Environmental Assessment "shall include brief discussions of . . . alternatives . . ." 40 C.F.R. § 1508.9(b).[1] Absent an analysis of an alternative based on a 150-foot southwesterly shift of the runway, without lengthening the runway, the EA is inadequate.

III. THE EA FAILS TO ADEQUATELY ANALYZE OR DISCLOSE THE PROJECT'S AIR QUALITY IMPACTS WHERE IT FAILS TO ADDRESS OR DETERMINE THE PROJECT'S CLEAN AIR ACT CONFORMITY.

Section 7506 of the Federal Clean Air Act [42 U.S.C. §§ 7401 *et seq*.] mandates that "[n]o department, agency, or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to [a State Implementation Plan] after it has been approved or promulgated under [42 U.S.C. § 7410]." The Environmental Protection Agency (EPA) has promulgated regulations implementing Section 7506 (the "Conformity Provision") in 40 C.F.R. §§ 93.150 *et seq*. ("General Conformity Rule"). The General Conformity Rule requires, in part, that Federal agencies first determine if a project is either exempt from conformity analysis or presumed to conform. If it is neither, the agency must conduct a conformity applicability analysis to determine if a full conformity determination is required. *See*, *Air Quality Procedures for Civilian Airports and Air Force Bases*, p. 13.

The project area, *i.e*., Washtenaw County, is in attainment for five of the seven criteria pollutants [p. 4-17], and marginal nonattainment for Ozone [p. C-3].[2] The area is designated as in nonattainment for PM2.5. [EA, p. C-4]. Therefore, one of the following applies:(1) the project is exempt from conformity; (2) the project is presumed to conform; or (3) the agency must conduct a conformity applicability analysis to determine if a conformity determination for PM2.5 is required. The EA does not indicate that any of the required actions was performed

As a threshold matter, the EA is internally inconsistent with regard to whether the Project is exempt or presumed to conform. At page C-4, the EA states unequivocally that "[f]or this

---

[1] Courts have consistently held that the "existence of reasonable but unexamined alternatives renders an EIS inadequate." *See, e.g.*, *Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998).

[2] The original six criteria pollutants are Ozone (O3), Particulate Matter (PM10), Carbon Monoxide (CO), Nitrogen Oxides (NO2), Sulfur Dioxide (SO2) and Lead (Pb). FAA Order 1050.1E ("Environmental Impacts; Policies and Procedures"), p. A-3, ¶ 2.1b, includes both PM10 and PM2.5 under the category Particulate Matter. On April 5, 2010 the EPA published Revisions to the General Conformity Regulations Final Rule [75 Fed. Reg. 17254-279 (2010)] which, among other things, added PM2.5 to the list of criteria pollutants in 40 C.F.R. § 93.153(b).

analysis it will be assumed that the project is neither exempt nor presumed to conform." [Emphasis added.] However, at page C-5 the EA states ". . . a conformity determination is not required and the proposed project is presumed to conform to the state implementation plan." [Emphasis added.] Under either scenario, however, the EA is deficient and fails to meet the "public disclosure" requirement under the National Environmental Policy Act ("NEPA"), 42 U.S.C. §§ 4321 *et seq*.

A. The EA Fails to Establish That the Project Is Exempt.

A federal agency has two options to determine that a project is exempt from conformity analysis: (1) if the project is included in the list of exempt actions listed in § 93.153(c)(2); or (2) if the project's total of direct and indirect emissions are below the emissions levels specified in § 95.153(b) of the Conformity Regulations ("*de minimis*"), § 93.153(c)(1).

The first option does not apply here because runway and taxiway extension projects such as the one described in the EA [p. 2-1] are not included in the exempt actions listed in Section 93.153(c)(2). Nor does the EA establish that the Project can be considered exempt as *de minimis* under 40 C.F.R. § 93.153(c)(1). The EA instead relies on the 1996 MDOT Bureau of Aeronautics Air Quality Study of seven general aviation airports (which notably do not include ARB) for the conclusion that "typical GA airports generate a low level of pollutants." [EA, p. 4-17]. From that nonspecific conclusion, the EA further generalizes to the assertion that, because ARB is comparable in size and activity to the seven airports studied, it can be assumed that emissions resulting from the Project will not exceed the conformity threshold levels, and, on that basis, concludes that a conformity analysis is not required.

This assumption is fatally flawed, however, for at least two reasons: (1) the EA does not quantify PM2.5 emissions from flight operations at ARB at all, relying exclusively on the 1996 Study; and (2) because there is no quantification, there is also no comparison with the explicit *de minimis* thresholds established in 40 C.F.R. § 93.153(c)(1). It is correct that the original version of 40 C.F.R. § 93.153(c)(1) did not establish explicit thresholds for PM2.5, as distinguished from PM10. However, the newly implemented revised General Conformity Rule does establish that distinction, and now serves as the template for the air quality analysis required in the EA. Moreover, FAA Order 1050.1E, Appendix A, p. A3, § 2.16 includes both PM10 and PM2.5 in "particulate matter."

B. The EA Fails to Establish That the Project Is Presumed to Conform.

The second option, the presumption of conformity does not apply here either. In July, 2007, the FAA published a "Federal Presumed to Conform Actions Under General Conformity Final Notice" [72 Fed.Reg. 41,565-580 (July 2007)] in which the FAA listed fifteen Airport Project categories which the FAA presumes to conform to applicable SIPs. The runway and taxiway extension project described in the EA does not fall within any of those presumed to conform categories. Therefore, the FAA cannot rely on the Presumed to Conform Final Notice to presume that the Project is in conformity.

C. The EA Fails to Establish the Project's Conformity Status.

Finally, even if, for argument's sake, the study of airports other than ARB were adequate for air quality analysis of ARB in the EA, the 1996 Study would be an inadequate substitute for the required analysis. 40 C.F.R. § 93.159 requires that analyses under the General Conformity Rule be based on, among other things: (1) "the latest planning assumptions," 93.159(a); and (2) "the latest and most accurate emissions estimation techniques available," 93.159(b). The 1996, 14-year old, Study patently fails to fall within either, let alone both, of these parameters.

In summary, the EA fails to establish the existence of any of the necessary components of the required finding of conformity for a Federal project, and, thus, is inadequate under both NEPA and the Clean Air Act.

IV. THE EA FAILS TO ACCOUNT FOR WELLS ON AIRPORT PROPERTY.

While Section 4.5.2 of the EA purports to address "Geology, Groundwater, and Soils" affected by the Project, it understates the significance of the fact that water resources are a principal use of the grounds where the airport is located.

"If there is the potential for contamination of an aquifer designated by the [EPA] as a sole or principal drinking water resource for the area, the responsible FAA official needs to consult with the EPA regional office, as required by section 1424(e) of the Safe Drinking Water Act, as amended." FAA Order 1050.1E, pp. A-74, 75, ¶ 17.1c. "When the thresholds indicate that the potential exists for significant water quality impacts, additional analysis in consultation with State or Federal agencies responsible for protecting water quality will be necessary. *Id.*, pp. A-75, A-76, ¶ 17.4a. "If the EA and early consultation [with the EPA] show that there is a potential for exceeding water quality standards [or] identify water quality problems that cannot be avoided or mitigated . . . an EIS may be required. *Id.*, pp. A-75, ¶ 17.3.

There are two issues raised by the Project that require further examination in the EA. First, there is the issue of contamination from the Airport. The Airport is the location of a porous sand/gravel formation that yields a large amount of water for pumping Historically, the land where the airport is located was originally acquired by the City of Ann Arbor for water rights in 1929. Until recently, 15% of Ann Arbor's water supply came from the three wells located on Airport property. Water Quality Report, 2008, City of Ann Arbor, p. 2 (available at http://www.a2gov.org/government/publicservices/water_treatment/documents/ccr.pdf). Due to the importance of the water supply at ARB, the EA needs to have more than a few passing words ("Based on coordination with the City of Ann Arbor, the proposed runway extension would not impact the water supply wells or the new water supply line (Bahl, 2009)"). [EA, p. 4-20].

Second, paving the area for a runway, roads, *etc.* increases the impervious area on the aquifer. This in turn reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer that is vital to the City of Ann Arbor. Further environmental review should provide detailed analyses of the impact of this increase in impervious surface, as well as the possibility of contamination, currently unexplored in the EA.

V. THE EA FAILS TO ANALYZE THE PRESENCE OF HAZARDOUS WILDLIFE NEAR THE AIRPORT AND FAILS TO PRESENT ANY MANDATORY MITIGATION MEASURES.

FAA Advisory Circular 150/5200-33B ["Hazardous Wildlife Attractants on or Near Airports"] contains standards for land uses that have the potential to attract hazardous wildlife on or near public-use airports. The standards are applicable to airport development projects, including airport construction, expansion and renovation. Airports that have received Federal grant-in-aid assistance must use these standards. [*See* AC 150/5200-33B, p. ii]. The FAA recommends separation distances of 5,000 feet at airports that do not sell Jet-A fuel, and 10,000 feet at airports that sell Jet-A fuel for hazardous wildlife attractants. [AC 150/5200-33B, p.1]. The Ann Arbor Municipal Airport sells both. The FAA also "recommends a distance of 5 statute miles between the farthest edge of the airport's AOA [Air Operations Area] and the hazardous wildlife attractant if the attractant could cause hazardous wildlife movement into or across the approach or departure airspace." [AC 150/5200-33B, p. 1]. Finally, AC 150/5200-33B provides that "[a]irport operators should identify hazardous wildlife attractants and any associated wildlife hazards during any planning process for new airport development projects" [p. 17] and "[t]he FAA will not approve the placement of airport development projects pertaining to aircraft movement in the vicinity of hazardous wildlife attractants without appropriate mitigating measures." pp. 17-18].

The FAA ranks geese as number three [3] in a list of the relative hazard to aircraft for 25 species groups. [AC 150/5200-33B, Table 1, p. iii]. However, the EA does not disclose that the area surrounding the airport is a prime habitat for large numbers of Canada Geese, which data clearly show it to be. More than a dozen Canada geese water habitats fall within the designated risk area (Exhibit 2), which are populated by numerous Canada geese much of the year (Exhibit 3 photographs), so much so that less than 1,000 feet from the Ann Arbor Municipal Airport itself, city officials must warn motorists of a Canada goose road crossing (Exhibit 4). And yet EA Appendix F lists 38 species of birds that have either been observed, or for which there has been confirmed or probable breeding in Airport fields during 2006 through 2008. And the list does not include Canada Geese. Canada Geese populate waterways on a golf course, in business parks and in neighboring wetlands located west and southwest of the airport, well within the separation distances prescribed by the FAA, as the exhibits document.

We raise the Canada geese issue because of growing safety concerns with respects to bird strikes in aviation. We know, for instance, that a 12-pound Canada goose struck by an aircraft traveling at 150 miles per hour has the kinetic energy impact of a 1,000 pound weight dropped from 10 feet. With more than 9,000 bird strike incidents in the U.S. last year (Associated Press, 2010), and seven reported in the history of the Ann Arbor Airport itself, it is a serious issue.

This type of risk contributed to the deaths of three passengers and two crew members in the crash of a Cessna Citation in Oklahoma City in 2008 because, according to the National Transportation Safety Board, a large bird hit the plane wing because the FAA had done an inadequate job of enforcement of wildlife hazard requirements (National Transportation Safety Board, 2009). With many large birds in the ARB area, in close proximity to many homes, at low altitudes of under 100 feet, citizens surrounding ARB do not want that type of disaster to be repeated here because of an ill-informed EA that ignores Canada geese.

It must be underscored that Canada geese were a subject of detailed communication between preparers of the EA and at least one member of the EA's Citizens Advisory Committee (CAC). CAC Committee Member Shlomo Castell, a commercial passenger airline pilot, requested that the EA's preparer, contractor JJR, collect papers from a national Birdstrike Prevention Forum in Chicago and, perhaps, seek the assistance of the panel's FAA liaison for a follow-up discussion with an FAA expert who presented important information at the conference for relevant Canada geese research. Mr. Castell's request was summarily rebuffed by JJR study coordinator Amy Eckland, writing, "The scope of this proposed project is to address the recommended runway length design parameters for the critical aircraft and to address line of sight issues from the tower. I will be meeting with CAC member and City of Ann Arbor Ornithologist, Dea Armstrong, to better understand the birds that are known to occur around the airport. Reviewing all of the information presented at the bird strike conference is an extensive inquiry that is beyond the scope of this project."

Mr. Castell followed up, explaining that in his view as a CAC member, bird strikes were environmental and a safety issue, and that as the only professional commercial passenger airline pilot on the panel he felt it important that such information be analyzed and that a "careful environmental study using FAA funds (via MDOT) would seriously consider the current work of the FAA's top bird strike expert." Mr. Castell went on to add: " . .In my flying career, I have encountered three bird strikes. The most severe one involved three geese on a final approach to Detroit in a Boeing 727. Their bones were later found in the wing's leading edge and flaps. Thankfully they were not ingested by the engines. Should something similar ever occur to a departing business jet, turbo-prop or light twin out of ARB, results will most likely be different."

But the subject was ignored by JJR, the EA and Ann Arbor.

Consequently, the preferred alternative (Build Alternative 3) would extend Runway 6/24 950 feet to the southwest. The extension would allow aircraft landing on Runway 6 and departing on Runway 24 to overfly areas populated by Canada Geese at altitudes of less than 100 feet. The EA does not consider this hazardous condition. Even though they are not designated as "special concern", "threatened" or "endangered," the presence of Canada Geese in the Airport area poses a hazard to aircraft operational safety, and should be identified and analyzed in the EA, along with proper mitigation measures.

VI. THE EA DOES NOT ACKNOWLEDGE OR ANALYZE THE PROJECT'S MANIFEST GROWTH-INDUCING IMPACTS.

A Federal agency is required to evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project [40 C.F.R., § 1508.8(b)] and increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). The "growth-inducing effects of [an] airport project appear to be its 'raison d'etre.'" *California v. U.S. D.O.T.*, 260 F.Supp.2d at 978, *citing City of Davis, supra*, 521 F.2d at 675. The EA ignores this requirement, even though the Project is virtually defined by its growth-inducing impacts. Despite the fact that the EA assumes that the "percent of night and jet operations would remain constant between the existing condition and the future years," [EA, p. 4-2] there is substantial evidence to indicate that the Project will cause a large increase in both types of operations.

As indicated above, there are no weight restrictions that must be lifted to allow the EA's "critical aircraft" to operate at ARB without weight restrictions. The "load restrictions" referenced on page 2-12 refer not to category B-II aircraft, but to the fact that higher category aircraft (jets in the C-I and C-II categories) must currently operate at reduced weights in order to use the current 3,505 foot runway. (Required takeoff length is the primary restrictor.) Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, all of which discourage these aircraft from conducting operations at ARB.

For example, a Cessna Citation II (Category B-II) requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and can operate at unrestricted weight from the existing 3,505 foot runway. A Lear 35 (Category C-I), on the other hand, requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,300 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be less than is currently required. Therefore, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Citation jet, which the EA states is a "critical aircraft."

The longer runway will facilitate the loading of additional passengers and baggage on high performance jet aircraft. Also, the ability to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. If the runway is lengthened to 4,300 feet, it is reasonably foreseeable that ARB will become much more attractive to operators of higher performance jet aircraft, such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II), who could then operate at ARB instead of driving to and from Willow Run Airport.

Contrary to the unsupported assertions in the EA [EA, p. 42; Appendix B-1, p. B-4], it is reasonably foreseeable that the fleet mix will change in favor of a higher percentage of jet operations as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft account for a high percentage of ARB operations. B-II aircraft account for a low percentage of ARB operations.

It is, therefore, reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer haul business jets often occur in the evening hours due to the longer time duration of their trips. Since one of the stated purposes of the EA is to increase interstate commerce, this is not merely an indirect, but also a direct effect, the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Thus, the evidence is clear that the Project will cause an increase in both jet *and* night operations. It is also reasonably foreseeable that these added high-performance jet aircraft operations and night operations will be accompanied by significant noise and air quality impacts. Nevertheless, the EA fails to acknowledge, let alone analyze, these reasonably foreseeable impacts caused by expansion of airport physical facilities and operational profile and, thus, is inadequate.

This is especially troublesome because these increased number of high-performance aircraft impact almost 10,000 citizens within Pittsfield Township and another 10,000 in surrounding communities and would cross over rooftops at projected altitudes of 93 feet when landing on an extended Runway 6 in densely populated neighborhoods.

VII. <u>POLITICAL JURISDICTIONS PROPOSED ACTION OR ALTERNATIVES WOULD IMPACT</u>

It is not surprising that Ann Arbor completely ignored the implications of its proposed actions or alternatives on the political jurisdictions affected, as described in Federal Aviation Administration Order 5050.4B in response to the National Environmental Policy Act, in its Environmental Assessment – and, in fact, omitted this section completely -- since the principal jurisdiction affected, Pittsfield Township, in which the airport is wholly located, has unanimously passed a Resolution to oppose the expansion and is strenuously fighting it. Neighboring Lodi Township has passed a similar Resolution opposing the expansion. That Ann Arbor continues its push to expand its airport in the face of such opposition represents an unconscionable, heavy-handed and perverse assertion of land rights despite the will of its neighbors, subjecting citizens of other communities to undue risks.

Worse, MDOT, which with its predecessor state agencies has been advocating the expansion of the Ann Arbor Airport's primary runway for almost four decades now, is charged under 49 USC 47128 with serving as the FAA's agent in Michigan but jeopardized its block grant status by taking an advocacy position, often abdicating its public agency obligation to represent all Michigan citizens and, instead, become a de facto sponsor of the Ann Arbor expansion. In so doing it subjects both the government of Pittsfield and the people of Pittsfield to untold potential future damage both in safety risks and in economic loss that could result in an effective taking of their property rights because of repeated low flying, heavy jet aircraft, forcing them to seek recovery in the event of a tragic accident or inverse condemnation class action proceedings, from Ann Arbor, a city already suffering from such financial difficulty that it could be unable to pay any significant damage awards. As such, Pittsfield victims would be left without effective remedy at law.

Thus, on behalf of the people of Pittsfield, Lodi, Ann Arbor, and Saline, the Committee for Preserving Community Quality seeks protection at the federal level to preserve the 14th Amendment rights of all area citizens, but notably Pittsfield citizens, and asks federal intervention to preserve their due process rights, since their local government is afforded no voice in the ultimate decision. Federal law, however, provides the Pittsfield government and citizens extraordinary petition rights direct to the U.S. Secretary of Transportation because their situation is so unusual and so serious (49 USC 47106 (C) (1) (iii)).

Pittsfield citizens would be subjected to a perfect storm of potential risks from low-flying aircraft in heavily populated neighborhoods that are also occupied by wildlife, including many Canada geese, during much of the year. This is confirmed by a study conducted by MDOT and Ann Arbor's own airport architects (URS Corporation) (Exhibit 5), which was excluded from the EA, and visualized on a projection of what the approach to an expanded Runway 6 would look like relative to the close proximity to area homes, which was corrected for accuracy (Exhibit 6).

An expanded Ann Arbor Municipal Airport would attract more jets of more types and bring multi-engine aircraft closer to heavily populated residential areas – within 600 yards at altitudes of 93 feet above rooftops of semi-luxury homes, or lower, on a regular, planned basis. Aircraft landing on Runway 6 would pass Lohr Road below 90 feet – the site of a new, planned non-motorized bike path, designated the Lohr-Textile Greenway Project, for which the Washtenaw County Parks and Recreation Commission has awarded Pittsfield a $ 300,000 Connecting Communities grant. Thus, low-flying, heavy jets would be landing just feet over people traversing a new non-motorized trail.

This is especially dangerous with heavier aircraft because, in the event of any common multi-engine aircraft mishaps -- such as an engine failure on takeoff, a bird strike on takeoff, climb out, or approach, or similar incident – with aircraft in very close proximity to homes, the risk could be grave – a perfect storm of environmental or human risk. Contrary to common belief, any twin-engine jet would lose 80 percent of its climb performance – and at low altitudes that could be tragic. In a light twin-engine aircraft, the consequences would be worse, because most will not continue to climb on one engine in takeoff configuration; neither can they turn back toward the airport at low altitude in takeoff configuration, which is why so many classically crash near airports.

This is no allusive fear. In June 2009, a small single-engine plane landing at the Ann Arbor Airport made an emergency landing 1,200 yards short of the field on a Stonebridge Golf Club fairway in Pittsfield after its engine died at low altitude on final approach. (Exhibit 7) The pilot said if there had been people on the fairway at the time, he would have "crashed into the trees," which would have probably been fatal for him and his grandson, whom he was instructing at the time (Wunderlich, 2008). And it is not insignificant that, between 1973 and 2001, nine people died from accidents flying in the Ann Arbor Airport traffic pattern within three miles of the airport (NTSB reports, 1973-2001). With the Ann Arbor runway moved 950 feet farther to the southwest and even closer to hundreds of homes, as proposed, and planes still lower on approach – and planes heavier, larger, carrying greater payloads, and more people – this poses a risk too grave to bring to a heavily populated community.

Such impacts and safety implications on political jurisdictions where airport decision-making bodies are absentees – and where local citizens and their governments have no say – must be investigated to protect the safety of all concerned. This was not done or addressed in the EA in any way.

VIII. NOISE MODELING FOR THE PROJECT FAILED TO INCLUDE INCREASED JET AIRCRAFT AND NIGHTTIME OPERATIONS IN DEVELOPING NOISE CONTOURS.

The FAA's Integrated Noise Model ("INM") was used to model annual operations for the 2009 existing condition, *i.e.*, April 2008 through March 2009 [EA Appendix B-1, p. B-4] and develop 65, 70 and 75 DNL noise contours for the Project. [EA, p. 4-3]. The EA states that "[t]he existing 65 DNL contour does not extend beyond airport property." [EA, p. 4-3]. During the time modeled, jet operations accounted for approximately 2 percent of total operations at ARB, and nighttime operations accounted for 4.2 percent of total operations. [EA, p. 4-2]. The EA states: (1) "[t]he percent of night and jet operations would remain constant between the existing condition and the future years"; (2) "fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives would remain static" [EA, p. 4-2; Appendix B-1, p. B-4]; and "[t]he ARB 2014 proposed project alternative DNL 65 dBA noise contour does not extend beyond airport property." [EA, p. B-6].

However, as shown in Section VI above, the Project will likely facilitate an increased number of night operations, and a change in fleet mix, which will include higher performance jet aircraft. DNL calculations depend on, among other things, forecast numbers of operations, operational fleet mix and times of operation (day verses night). [EA, Appendix B-2, p. B-16]. However, the EA fails to model or assess future increased night operations and fleet mix changes resulting from the Project.

The FAA is required to use INM to produce, among other things: (1) noise contours at the DNL 75 dB, DNL 70 dB and DNL 65 dB levels; (2) analysis within the proposed alternative DNL 65 dB contour to identify noise sensitive areas where noise will increase by DNL 1.5 dB;[3] and (3) analysis within the ***DNL 60-65 dB contours*** to identify noise sensitive areas where noise will increase by DNL 3dB, ***if*** DNL 1.5 dB increases as documented within the DNL 65 dB contour. [FAA Order 1050.1E, Appendix A, p. A-62, ¶ 14.4d].

As the noise modeling failed to take into account the foreseeable increases in nighttime

[3] A significant noise impact would occur if analysis shows that the proposed action will cause noise sensitive areas to experience an increase in noise of DNL 1.5 dB or more at or above DNL 65 dB noise exposure when compared to the no action alternative for the same timeframe." [FAA Order 1050.1E, Appendix A, P. A-61, ¶ 14.3]

and jet aircraft operations at ARB, the questions of whether the future DNL 65 dB contour will be increased, and to what extent, and whether increased noise levels within the DNL 65 dB contour would necessitate designation of a DNL 60 dB contour remain unanswered.

IX. PROCEDURAL JUSTICE.

For 40 months, the Ann Arbor Municipal Airport expansion proposal has been in the works. Most of that time, it has been clouded in injustice. A long line of Procedural Justice violations began with the birth of the expansion proposal by Ann Arbor on January 22, 2007. On that day, the Ann Arbor City Council unanimously approved Resolution R-31-1-07, formally adopting the airport's previous Airport Layout Plan (ALP) and ordering the city staff to return with a separate proposal to expand the airport's primary runway within 60 days and that "notification of the proposal be sent out to citizens in the surrounding area."

Not only did the Ann Arbor city staff not return to its City Council with an expansion proposal within 60 days, it did not share such a proposal with neighboring citizens such as Pittsfield as required by its Council's order. Instead, however, just 37 days after its initial City Council Resolution order, on February 28, 2007, the city of Ann Arbor secretly submitted to MDOT-AERO a proposal for an 800-foot extension of primary runway 06-24 at Ann Arbor Municipal Airport – essentially, the present proposal being considered by the FAA. No corresponding notice was given to Pittsfield.

Thus began a plan by an overzealous Ann Arbor City Administration and Airport Manager run amok, beyond the control and limits of even its own elected officials and their mandates, in what amounted to an illegal and systematic effort to evade and elude any type of public disclosure about its airport expansion plans, regardless of the legal and political consequences.

On September 12, 2007, the proposed ALP was amended at the request of MDOT to allow for the 150-foot southwesterly movement of the entire primary runway, to provide for the eventual widening of State Street-State Road, which MDOT concedes cannot be funded for decades. Still, Pittsfield had not been informed by the applicant or MDOT about the proposed expansion on land within its jurisdiction, even though the Airport Emergency Plan calls for Pittsfield to provide primary Fire and Rescue Protection at the airport.

On April 23, 2008, MDOT approved the revised Ann Arbor Airport ALP. The state review had taken 420 days.

On June 4, 2008, the FAA's review of the Ann Arbor Airport ALP was begun by Cheri Walter, an Airspace Program Manager of the FAA. On the day she began her review, Ann Arbor Airport Manager Matt Kulhanek wrote her the following:

> Cheri: Wow! I can't tell you how much I appreciate your timely response to our review. I was happy to just hear that you were moving it to the top of the pile. For you to be that responsive to our local concerns reflects someone with a good heart who truly wants to serve their customers. I can honestly say that I have never received such a high

> level of service from the FAA. I would be honored to share that with your supervisor if you want to provide me with the contact information. Again, thank you so much. I hope that at some point in the near future, this action assists us in providing a longer and safer runway for the aviation community. Have a great day! (Kulhanek, 2008.)

Ms. Walter responded early the next morning with a note of thanks and the e-mail address of her supervisor, John Weizenbach, to whom Mr. Kulhanek wrote on the following day:

> Mr. Weizenbach, I wanted to send you a short email to inform you of the excellent customer service I recently received from a member of your staff, Cheri Walter. Ms. Walter was assigned the airway facilities review for the Ann Arbor (MI) Layout Plan update. Unfortunately, the ALP update had taken an extended period of time through MDOT staff. This delay was causing timing and political issues on our proposed runway extension project. I was able to explain this to Ms. Walter whose response was remarkable. She located our plan and completed the review in a very timely manner. This quick turnaround from the FAA will greatly aid the success of our proposed project. Ms. Walter was pleasant, accommodating and very open to our local concerns. As a customer of the FAA, I could not have asked for better service. You should be very proud to have someone like Ms. Walter on your staff and representing the FAA in such a positive way. Have a great day. (Kulhanek, 2008.)

Not surprisingly, the FAA approved the Ann Arbor ALP on June 23, 2008 – just 19 days after the review was begun, less than 1/20th the time the state review took, and after the e-mail exchange of praise between the Ann Arbor Airport manager and the FAA reviewer. And, still, Pittsfield had not been officially notified about the expansion proposal.

On August 22, 2008, Ann Arbor first officially provided Pittsfield plans and notification of the proposed ARB expansion and detailed proposed changes in the ALP. These documents were required to be provided more than 18 months earlier under both the January 2007 Ann Arbor City Council Resolution mentioned hereinabove and under a separate 1979 Policy Statement referenced by the Ann Arbor official authoring the letter. It is noteworthy, that this first notification from Ann Arbor to Pittsfield is dated 59 days after the FAA approved the revised Ann Arbor Airport ALP. Under 49 USC 46110, routine federal court appeals are barred after 60 days. Thus, Pittsfield was effectively barred from legally objecting to the Ann Arbor ALP before even being notified by Ann Arbor about its revised ALP.

Pittsfield responded to Ann Arbor's August notice, objecting to the proposed expansion, citing the (1) increased noise that would be generated, (2) larger aircraft that would be attracted, and (3) and greater use by heavier aircraft that could result. Pittsfield subsequently unanimously Resolved (March 24, 2009) to oppose any expansion of the Ann Arbor Municipal Airport. Lodi Township subsequently passed a similar Resolution.

The Ann Arbor City Council approved the revised Ann Arbor ALP on September 22, 2008, without considering Pittsfield's objections, or those of Lodi Township.

Subsequently, in Spring 2009, a Citizens Advisory Committee (CAC) was appointed to advise the preparers of the Environmental Assessment submitted by Ann Arbor. The CAC was initially comprised of:

- The Ann Arbor Airport manager.
- The chairman of Ann Arbor's Airport Advisory Committee.
- An Ann Arbor 4th Ward resident, who is also a member of the Airport Advisory Committee.
- An Ann Arbor 3rd Ward resident, who is also a flight instructor at the airport.
- Another pilot based at the airport, who is also chief pilot of Avfuel, which operates the Cessna Citation 560 Excel based at the airport, which stands to be the single greatest beneficiary from the runway extension.
- Another airport flight instructor, who is also a member of the airport-based FAA Safety Team.
- A citizen member from Ann Arbor's 5th Ward.
- A representative from Ann Arbor's 2nd Ward, who is also a member of the Ann Arbor City Council.
- A representative of the Washtenaw Audubon Society, which conducted a previous study that found no Canada geese among 38 other species on the airport.
- Lodi Township Supervisor Jan Godek.
- Pittsfield Township Deputy Supervisor Barbara Fuller.

It was only after extensive political pressure that two additional outside members were added to the CAC:

- Shlomo Castell, a commercial passenger airline pilot from the Stonebridge Community Association in Pittsfield Township, and
- Kristin Judge, Washtenaw County Commissioner from District 7, which includes Pittsfield.

Even so, for an airport located in Pittsfield Township that most dramatically impacts Pittsfield and Lodi Townships and Ward 4 of Ann Arbor, the CAC was dominated by Ann Arbor and airport members who stood to benefit from the expansion and the CAC was under-represented by those immediately outside the airport perimeter whose safety could be placed at greater risk by any expansion. The Environmental Assessment never addressed nor studied the safety implications of any such expansion.

Throughout the process, the only opportunity for any public discussion -- with elected public officials present -- about the proposed expansion plan was before the Ann Arbor City Council, where speakers must call-in to register in advance. Only the first ten callers on the day of Council meetings are permitted to speak. Speakers are limited to three minutes. Such a process typically has a stifling effect on open and candid discussions for subjects as complex as an airport ALP and runway expansion proposal.

To satisfy the federal "Public Hearing" requirement, MDOT and Ann Arbor devised an equally stifling process. On March 31, 2010, a three-hour "open house" was held during the dinner hour period between 4-7 pm, during which individuals could assemble and provide public comments in response to the Environmental Assessment. Local media announcements of the event (AnnArbor.com) encouraged citizens to send Environmental Assessment comment letters directly to the Airport Manager, rather than MDOT, until Respondents intervened and requested that MDOT correct the process to restore a semblance of fairness. At the session itself, there was no dias of public officials impaneled. There were no open, public statements with the media present. All testimony was given in private rooms to court reporters, to be forwarded to MDOT for later evaluation and, presumably, incorporation into some finalized Environmental Assessment.

That citizens, not public officials, needed to police the process was the ultimate insult to ensure any semblance of fairness and equity. By this public hearing process being so restricted, members of the public were effectively deprived of their due process rights under the 14th Amendment of the U.S. Constitution to ever have an opportunity to speak in an open and fair forum in a reasonable amount of time in opposition to the airport expansion before a public body. That is because, if the expansion proposal goes forward, the Ann Arbor City Council generally restricts all outside speakers to three minutes, which is hardly an adequate time to offer an organized and coherent argument against such a complex proposition as an airport expansion, whereas – at the same time – city officials and their surrogates are afforded unlimited time to speak to the City Council to advocate in favor of the runway expansion, in clear violation to due process protections. Thus, by closing off the fairness and balance intended by this only federally-mandated forum, related to EA comments, stifled the only open public commentary and dissent regarding the airport, in violation of the law.

IX. CONCLUSION.

Given the Project's many potential significant environmental impacts that have not been identified or fully analyzed in the EA, the substantial potential risks to human and environmental life living in the vicinity of the airport that have not been properly studied and are placed at risk by the proposed expansion, it should be rejected. At minimum, a full Environmental Impact Statement (EIS) is required prior to approval and implementation of the Project. "No matter how thorough, an EA can never substitute for preparation of an EIS, if the proposed action could significantly affect the environment." *Anderson v. Evans*, 371 F.3d 475, 494 (9th Cir. 2004).

Sincerely,

Andrew R. McGill, Ph.D.

Williams Aviation Consultants

Williams Aviation Consultants, Inc. was retained by the law firm of Chevalier, Allen & Lichman, LLP to review and comment on Chapters 1 and 2, and Appendices A and B of the DRAFT Ann Arbor Municipal Airport Environmental Assessment (DEA), February, 2010. The following are our comments on the DEA.

A. Accommodating the Critical Aircraft at Ann Arbor Municipal Airport (ARB)

As stated in paragraph 2.2.7, "*The proposed shift and extension of primary Runway 6/24 at ARB would provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility.* (Emphasis added)

In particular, the proposed project would provide the following benefits:

- *Enhance business aviation and interstate commerce by providing sufficient runway length to allow the majority of category B-II Small critical aircraft that currently use ARB to operate without load restrictions (i.e. reduction in passengers, cargo, and fuel associated with aircraft range).* (Emphasis added)

According to paragraph 2.2, Purpose and Need, "The purpose of the proposed improvements at ARB is to provide facilities that more effectively and efficiently *accommodate the critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport. (Emphasis added)

The critical aircraft is defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the critical aircraft weigh less than 60,000 lbs, a classification of aircraft is used rather than a specific individual aircraft model. A recent Airport User Survey has confirmed that the critical aircraft classification for ARB is "*B-II Small Aircraft*." (Emphasis added)

Also stated under "Purpose and Need" "*Development of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions).* (Emphasis added)

WAC Comment: There are no aircraft in the B-II Small aircraft classification that require a runway length of 4,300 feet to conduct normal operations. All B-II Small Aircraft are capable of operating out of the current runway (3,505 feet long) without the need to reduce weight by off-loading passengers, baggage or fuel.

Regarding the establishment of the critical aircraft, ARB lacks the required number of 500 annual operations by B-II Small Aircraft, so they have added larger aircraft such as B-II Large, Category C-I and C-II operations to meet the 500 classification requirement. It is the Category C-I and C-II aircraft which would benefit by the runway extension to 4,300 feet, not

8490 South Power Road, Suite 105-181 • Gilbert, AZ 85297 • Office (480) 987-7823 • Fax (602) 513-7388

those aircraft that fall within the definition of Category B-II Small Aircraft. The current runway length of 3,500 feet is sufficient to handle all Category B-II Small Aircraft.

B. Lengthening Runway 6/24 to 4,300 Feet: The Impact on Aircraft Load Restrictions and Fleet Mix

The "load restrictions" referenced above in paragraph 2.2.7 refer to the fact that the higher category aircraft (primarily jets in the C-I and C-II categories) must currently operate at reduced weights in order to operate out of the current 3,500 foot runway (required takeoff length is the primary restrictor). Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel; all of which discourage these aircraft from conducting operations out of ARB.

For example: A Cessna Citation II (Category B-II) requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day and may therefore operate unrestricted as to weight from the current 3,500 foot runway. A Lear 35 (Category C-I) requires 5,000 feet for takeoff at maximum certificated gross weight on the same standard day.

The Category B-II Citation II can conduct unrestricted operations from the current 3,500 foot runway. Whereas extending the runway to 4,300 feet would not facilitate unrestricted operations by the Category C–I, Lear 35, the required weight reduction would be less than is currently required. In this way, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide no operational benefit to the Category B-II Small Citation jet, or any other Category B-II Small aircraft.

All Category B-II Small aircraft, i.e. the ARB critical design aircraft, are currently accommodated on the existing 3,500 foot runway. Contrary to what is stated in the DEA, lengthening the runway to 4,300 feet WOULD NOT "provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility."

If the runway is lengthened to 4,300 feet, other jets such as the Lear 25 (Category C-I), Cessna Citation III (Category C-II) and Cessna Citation Sovereign (Category C-II) may be able to operate out of ARB with minor reductions in takeoff weight. This will impact the community as it could reasonably be expected that the longer runway will attract more of the larger, higher performance jet aircraft to the airport.

These added high performance jet aircraft operations will be accompanied by noise and air quality impacts. Many of these operations will take place at night, thereby negatively affecting the general quiet of the surrounding community.

C. Shifting Runway 6/24 150 Feet to the West While Maintaining the Current Runway Length of 3,500 Feet: The Impact on Load Restrictions, Future Fleet Mix and Safety of Operations

Load Restrictions

Maintaining the current runway length of 3,500 feet would mean that the Category C-1 and C-II aircraft would continue to suffer significant load restrictions. These load restrictions would thereby continue to serve as a deterrent to these aircraft operating out of ARB.

Future Fleet Mix

Maintaining the current runway length would serve to maintain the current fleet mix. Category B-II Small jet aircraft include lower powered models such as the smaller versions of the Cessna Citation (Category B-I/II) and the Mitsubishi Diamond jet (Category B-I). Higher powered jet aircraft such as the Lear 25 (Category C-I), Lear 35 (Category C-I), IAI Astra (Category C-I) and Cessna Citation III (Category C-II) may be generally discouraged from flying into Ann Arbor and would generally, with few exceptions choose to land at Detroit and drive the 40 miles to Ann Arbor.

Safety of Operations

2.2.1 Safety Enhancements:

In the first paragraph, the consultant is correct in stating that shifting the Runway 24 threshold 150 feet west would enhance safety by effectively removing the current obstruction to line-of-site vision (hangar) of the parallel taxiway for ATCT personnel.

However, in the next paragraph the consultant states, "The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles."

This statement betrays a lack of understanding by the consultant of Instrument Approach Procedure (IAP) design and TERPS Obstruction Standards. Regarding the 20:1 and the 34:1 surfaces; it is not either/or, but both/and. Both the 20:1 and the 34:1 surfaces exist simultaneously for every published IAP and are defined as "Obstacle Identification Surfaces" which do not establish obstacle clearance safety margins but rather only define instrument approach visibility minimums. The FAA does not require either of these two surfaces to be free of penetration by obstacles, and thus "providing an additional margin of safety" as stated by the consultant does not apply in the case of these two surfaces.

Other TERPS surfaces (Obstacle Clearance Surfaces) are established which do ensure clearance from obstructions and the FAA requires that these Obstacle Clearance Surfaces be clear of structures and terrain. The current IAPs to Runway 24 were designed by the

FAA to accommodate all existing obstructions. In this respect, shifting the runway 150' to the west would not enhance safety.

Summary: Assuming that the consultant is correct in their assertion that shifting the threshold would eliminate obstruction penetrations to the existing 34:1 Obstacle Identification Surface, the effect would not be a safety improvement but would only result in a reduction in the required approach visibility minimums.

D. Appendix B Noise Analysis Report
B-1 Noise Impact Analysis
B.1.3 Data
Flight Operations

The consultant states "INM-modeled annual operations for the 2009 existing condition, consisting of operations from April 2008 through March 2009, totaled 61,969 operations, which is approximately 169 daily operations. Jet operations accounted for approximately 2 percent of the total operations. Nighttime operations accounted for 4.2 percent of the total operations."

2014 future condition aircraft operations were obtained from the 2008 FAA TAF for ARB. Modeled annual operations for the 2014 condition totaled 69,717 operations, or approximately 191 daily operations. *It is assumed that the percent of night and jet operations will remain constant between the existing condition and the future years. In addition, it is also assumed that the fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives will remain static.* The existing and future fleet mix with annual operations is shown in Table B-2." (Emphasis added)

The consultant wrongly assumes that the percent of night and jet operations will remain constant, and that the fleet mix will remain static if Runway 6/24 is lengthened to 4,300 feet.

The longer runway will make ARB much more attractive to larger and higher performance jet aircraft as the added runway length will facilitate the loading of additional passengers and baggage on to these aircraft. Also, being able to carry additional fuel may mean that, in certain cases, costly and time consuming intermediate fuel stops will become unnecessary. As ARB becomes more attractive to higher performance jet aircraft, these larger aircraft may then consider operations to/from ARB in lieu of landing at Detroit and driving to Ann Arbor.

As more high performance jet aircraft begin operations at ARB, the fleet mix will change in favor of a higher percentage of jet operations as compared to the current level of light single and multiengine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft currently reflect a high percentage of ARB operations. B-II Small aircraft (the critical design aircraft) reflect a low percentage of ARB operations. Recall that Category B-II Large and Category C aircraft had to be added to the currently operating Category B-II Small aircraft design group in order to meet the 500 operation requirement for establishing the critical aircraft and thereby justify the runway extension.

The number of night operations also has the strong potential to increase as the number of arrivals of the larger, longer haul business jets often occur in the evening hours due to the longer time duration of their trips. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

Re: Ann Arbor Municipal Airport, Environmental Assessment

Dear Ms. Lamrouex:

This office has completed a review of the subject document received by this office on April 07, 2010. This review only took under consideration the sections that were in regard to water resources.

As a result of this review the following comments are offered:

1. The Wood Outlet Drain, a designated county drain, extends approximately 1,000 linear feet further to the north than is shown in Figure 4.8.
2. It is indicated that build alternative 3 is the preferred alternative. This alternative extends the runway 950 linear feet to the west.
3. It is indicated that the preferred alternative does not impact the stream that is existing on the site. Using GIS measurements it appears that the stream is less than 1,000 linear feet from the existing runway. The runway extension would bring this infrastructure within 50 linear feet or less of the stream. In addition to this the grading limits shown in Appendix D-7 clearly extend into and beyond the location of the stream. Based on this information it is not understood how it has been concluded that there are no impacts to the stream.
4. It is indicated that the preferred alternative does not impact the floodplain for the stream that is existing on the site. It is indicated that proposed grading for the expansion would not occur within the designated floodplain boundary. Based on the floodplain boundary shown on FEMA Community-Panel Number: 260623 0010 C these statements are incorrect. Not only do the grading limits indicated for the preferred alternative extend into the floodplain boundary but the runway extension itself will extend into this floodplain

boundary. Based on this information it is not understood how it has been concluded that there are no impacts to the floodplain.

5. It is noted in the report that: "The amount of impervious surface on site would increase slightly due to the extension of the runway and taxiway from the existing 7 percent of the 837 acres to 7.4 percent." This slight increase noted equates to an additional 3.348 acres or 145,839 square feet. This increase in impervious surface is considered by this office to be significant and not slight particularly knowing that the additional runoff from this area will discharge to the Wood Outlet Drain.
6. It is noted in the report that: "Implementation of appropriate best management practices (BMPs) would continue to control the rate of stormwater runoff and maintain water quality standards." It is unknown by this office as to what the control rate of stormwater is currently being implemented or whether this rate meets county standards.   The additional volume created by this increase in imperviousness is not spoken to at all by the report. The type or locations of the appropriate BMPs indicated are not identified.

If you would like to discuss these issues please contact me.

Sincerely,

Dennis M. Wojcik, P.E.
Chief Deputy Water Resources Commissioner

Subject: Draft Environmental Assessment for Ann Arbor Municipal Airport
Federal Aviation Administration Review Comments

Dear Ms. Lamrouex:

We have completed a review of the draft Environmental Assessment (EA) submitted to the Federal Aviation Administration (FAA) Detroit Airports District Office (ADO). Based on our review the FAA offers the following.

Air Traffic offers the following comments:

No comments.

Tech Ops offers the following comments:

Cover sheet. If the document is to be accepted as a federal document the coversheet will need to reflect this.

Section 2.1. Second bullet states "Shift and extend the parallel taxiway to coincide with the revised Runway 6/24". We recommend *revised* be changed to *extended*.

Section 2.2. This section does not appear to clearly state the need for the proposed action. Are the bulleted "objectives of the proposed project" actually proposed actions? The last bullet states "Relocate and potentially upgrade the Runway 24 Approach Light System". When will it be known if the approach light system will be replaced or upgraded? What is this dependent on? The remainder of the document deals with the impact of the runway extension, but does not address impacts related to the relocation of the existing light system or an upgrade to a new system. Also, action associated with Runway End Identifier Lights (REIL) is mentioned later in Section 4.17 and should be listed here as a proposed action. Are there any other NAVAIDs moving or being established?

Section 2.2.1. This section states that the Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF) would serve the same function as the Omni-Directional Approach Lighting System (ODALS) and is structurally very similar. How would the footprint of the MALSF structures compare to the ODALS? What environmental impacts would installation of a MALSF create?

Section 3.1.2. We suggest adding a qualifier in the second paragraph to state the following: "...would be greater than those expected with the *proposed* expansion of ARB in its current location."

Section 4.4. The Consequences of the Preferred Alternative section states: "Comparisons of existing conditions at various airports with future build out conditions indicate that the net change in air emission is still below standards." Do these *conditions* include runway extension projects similar to the proposed action at ARB?

This section additionally states: "Consequently, the air model results for the Preferred Alternative would be identical to those for the No Build Condition." This statement implies that no air emissions would result from the proposed action. Is this accurate?

Section 4.5.1. Would the existing Storm Water Pollution Prevention Program cover the additional impervious surface area?

Section 4.5.2. We would recommend rewording the first sentence of the Consequences of the Preferred Alternative section to the following (if true and appropriate): *Surface and subsurface geological conditions would not be impacted by the Preferred Alternative.*

Flight Procedures offers the following comments:

No comments were provided by Flight Procedures Office (FPO).

However, it should be noted that the FPO must be notified by formal letter to request the development of future approach procedures for the relocated runway end coordinates. Information needed includes identification of when construction will start, finish, when the equipment will be relocated, etc. This information is critical for developing/amending approach procedures. The FPO must know the project phasing in order to have procedures ready when construction is complete. (Equipment relocation, threshold displacements, etc). Changes in runway pavement length will result in survey data. Please note that survey data must meet the specifications outlined in Advisory Circulars 150/5300-16, 17, and 18. Third party surveys must be coordinated with the FPO. The proponent must submit Proposed Equipment Relocation Data along with information related to any equipment that will be relocated or added to AVN-210 and ATA-110. 7. Publication of new/amended Approach Procedures could take from 18 months to 2 years after runway data is submitted to AVN-210 and ATA-110. NOTE: Development of Approach Procedures will not begin until an official letter of request for development of procedures is received by FPO and the proposed runway data and equipment data provided to AVN-210 and ATA-110. Proponent must update the airport FAA Form 5010-1 to reflect new runway data and updated runway changes.

Airports Division offers the following comments:

The report is not clear if there is a federal action being requested.

Based on the information contained within the draft EA it appears that at least two federal actions are being requested. These actions include the relocation or replacement of the current approach lighting system as well as the development for future approach procedures for the new runway end locations. The FAA recommends that these actions be clearly identified throughout the document. The first page of the document states that this draft EA will become a State of Michigan document when signed by the State Official and does not include similar language for the Federal Aviation Administration although there is a signature line included for a federal official. Please refer to FAA Order 5050.4B section 707(f).

Section 1 page 1-1. The draft EA states that the projects under consideration are those shown on the FAA approved Airport Layout Plan (ALP). This statement should be clarified as to the role of Michigan Department of Transportation (MDOT) in conditionally approving the ALP set on behalf of the FAA under the authority of the State Block Grant Program. When referencing the ALP throughout the document, additional emphasis should be made to the June 23, 2008 ALP approval letter that clearly states that the approval is conditional. Several conditions were placed on the approval letter including the requirements that the projects contained within the ALP set must comply with the National Environmental Policy Act (NEPA). The FAA recommends inclusion of the conditional ALP approval letter in the draft EA for disclosure purposes.

We also suggest the executive summary clearly outline who will be responsible for actions associated with the proposed project (i.e. local sponsor, local unit of government, State of Michigan, Federal Government). For the FAA to co-sign the document, the requested Federal Actions must be clearly identified within the executive summary and throughout the document where appropriate.

Section 2 page 2-1. References to the ALP set need to clarify that MDOT has only conditionally approved the ALP.

Section 2.2 page 2-4. The classification of a B-II Small Aircraft has been determined with a reference to MDOT 2009. Is the B-II "Small Aircraft" a designation that is contained within MDOT planning guidance? The FAA is not familiar with the classification of "small" when identifying the critical design aircraft for an airport. Please clarify how this distinction was derived.

Section 2.2 page 2-4. The paragraph discussing Origin-Destination Analysis should be expanded (or references made where information can be reviewed) to provide clarification to the general statements that are made. Specifically, is there a list of destinations that can be provided that will substantiate the need for a runway extension? A listing of destinations may aid the reader in putting the proposed project into perspective and may further substantiate the need for a runway extension. The report states that a significant number of operations occur between ARB and distant locations without quantifying the number and types of operations that are being referenced. The FAA recommends this be clarified in the report or referenced to the appropriate appendices.

Section 2.2 page 2-5. Are the bulleted items for the objectives of the proposed project presented in order of relative importance?

The statement that the project will enhance interstate commerce does not appear to be substantiated by supporting documentation here or elsewhere in the document. How has this been verified? What are the enhancements? Is this a need for the project? The FAA recommends referring to FAA Orders and Advisory Circulars that address runway length, operational capacity of the aircraft utilizing ARB, and any deficiencies that currently exist at ARB that are a function of the current runway length. Without a detailed discussion and explanation of what the interstate commerce enhancement is and how this has been quantified as a current need, the FAA does not recognize this as a need for the project based on the information provided.

If enhancing interstate commerce is a stated need for the project then the report should be expanded to include a full range of alternatives that can address this need including alternative modes of transportation as an example.

The last bulleted objective in this section is for the relocation and potential upgrade of the Runway 24 approach lighting system. The report does not appear to document why this is a need for the project or if the approach lighting system is currently required or needed in the future.

What benefit does the current approach lighting system provide the airport? There does not appear to be a credit for a reduction in minimums at the airport as a result of having the ODALS. Has a Benefit Cost Analysis (BCA) been completed or requested of the FAA substantiating the need for relocating or replacing the ODALS? Depending on the results of the BCA and associated justification for relocating the existing or installing a replacement light lane at ARB, the potential exists that the Federal Action may be limited to abandoning the existing ODALS and no relocation or replacement would occur with federal funds.

Section 2.2.1 page 2-5. The first paragraph implies that runway incursions have been occurring at ARB as a result of issues with the current line of sight between the ATCT and a portion of the taxiway system and taxiway hold area. The report further indicates that the proposed project will possibly prevent incursions from occurring. Are there any documented runway incursions resulting from the current line of sight issue that can be included in the report to substantiate this claim? The FAA supports safety enhancement projects and would consider this a measure to improve the line of sight from the ATCT to parallel taxiway and the hold area if it can be demonstrated that the existing condition contributes to runway incursions. While a goal of the FAA is to reduce the number of runway incursions at airports nationwide, the FAA can not definitively conclude that this proposed safety enhancement at ARB will potentially *prevent* runway incursions but rather if the line of sight issue is improved this may *reduce the possibility* of runway incursions.

This section includes discussion of the potential to achieve a clear 34:1 approach and reduce minimums at the airport. The ADO previously requested clarification on this issue in an e-mail dated March 4, 2010 (attached for reference). Based on the e-mail exchange, the FAA understands there is no anticipation of a reducing of minimums at this airport for the foreseeable planning future.

Since minimums will not be reduced as a result of the project, the FAA is unclear on the need for a 34:1 approach or how it enhances safety of the approach procedures currently published for the airport based on the existing 20:1 approaches. The document should better explain how providing a 34:1 approach enhances safety for the existing and future users at the airport or how this also may impact interstate commerce. Has the current 20:1 clear approach resulted in missed approaches that have been documented? If so how often does this condition occur?

Is providing clear 34:1 approaches a project need or a benefit that may result from the relocation of the runway? Earlier in the report it was identified as a stated objective, however, the discussion in the report does not appear to substantiate the need for this when combined with the e-mail exchange of March 4, 2010 and conditionally approved ALP dated June 23, 2008.

While the future 34:1 approaches are identified on the conditionally approved ALP, it should be noted that this would result in an expansion of the approach surface from the existing 500'x2,000'x5,000' to 500'x3,500'x10,000'. The EA needs to fully disclose the increase in the approach surface if a 34:1 approach is achieved and document any environmental impacts that result from the larger approach surface.

Section 2.2.2 page 2-6. It is not clear to the FAA why there is a summary of Wings of Mercy operations since 1992 including 51 flights reported in 2009. This data appears to be in addition to what was collected as part of the user survey report that relied predominately on information from calendar year 2007. What is the relevance of including the 2009 data or specifically identifying the Wings of Mercy flight operations? Are there a range of aircraft types that fly for Wings of Mercy? Does the proposed runway extension impact their operational capacity?

Section 2.2.2 page 2-7. Discussion on the Michigan State System Plan (MASP) identifies the airport reference code (ARC) as B-II. Does the MASP differentiate between B-II small and B-II large? In absence of a clearly defined category of B-II "small aircraft", the FAA would suggest simply referring to the airport with a B-II ARC.

Section 2.2.3 pages 2-7 and 2-8. This section most clearly identifies why a runway extension is being proposed in accordance with FAA advisory circulars and State standards outlined in the 2008 MASP. This section, in combination with section 2.2.4 that documents substantial use (i.e. over 500 annual operations) by the B-II critical design family of aircraft appears to substantiate the justification for the runway extension based on the 2007 operational data.

Section 2.2.4 page 2-9. Detailed operational information is presented for calendar year 2007. Subsequent years are generalized based on trend analysis and overall decrease in operations as reported in the FAA Terminal Area Forecast (TAF). There does not appear to be an evaluation to account for the 21.8% decrease in operations between 2007 and 2009. Would it be prudent to verify if the operational decrease impacted one user group more than other user groups? Are the numbers of local and itinerant operations decreasing at the same rate or is one segment impacted to a greater extent? This evaluation may be accomplished through additional user survey data collection or potentially from the ATCT located at ARB for subsequent years since 2007. Additionally, the FAA recommends that the year of the TAF being utilized for this report be identified.

Section 2.2.4 page 2-11. Specific information for AvFuel Corporation is presented to validate assumptions for the continued classification of the airport as B-II. It should be noted that AvFuel bases a Citation 560 Excel jet at ARB and is designated in the report as a B-II "*Large*" aircraft. The discussion further indicates that the Chief Pilot submitted written documentation regarding potential future operational levels at ARB. The written documentation does not appear to be included within the report or appendices. However, according to the text in the report, the Chief Pilot anticipates future operational levels increasing to 350-450 annual operations. This level of use, in combination with a limited number of additional similar B-II aircraft would appear to classify the airport as a B-II "*Large*" designation. The FAA reiterates the hesitation on identification of either a "small" or "large" within an airport reference code and recommends that any qualifier to the size of the B-II critical design aircraft be removed from the report. The number of operations forecasted to occur by AvFuel Corporation would further support the elimination of the qualifier as "small" to the ARC.

Section 2.2.6 page 2-12. The local objective of reducing runway overrun incidents appears to conclude that if the added runway length were present, all the incidents would have been avoided. Based on information presented, the FAA does not necessarily come to the same conclusion. There are many factors that go into any overrun incident and if additional runway length were present this may have only prolonged the overrun incident. The A-I category of aircraft involved with overrun incidents do not appear to have needed any length beyond the existing runway length to operate at full capacity and in a safe manner.

The paragraph that references Accelerated Stop Distance Available (ASDA) requirements appear to include fleet mixes other than A-I and implies that aircraft can accommodate their operational requirements with a reduced load capacity. The ADO is not aware of any A-I aircraft operating at ARB that would need to operate at a reduced load capacity to adequately satisfy their calculations for safely operating at ARB.

It is not clear when the 11 overrun incidents occurred, their cause, or conclusions that support that runway length was a factor in the overrun incidents. Can additional information be provided to support this position? If additional information is not available the FAA recommends removing this section from the document.

The FAA recognizes that this section of the report was included as a local objective and it is clearly and appropriately stated that the FAA does not recognize this as a need for extending the runway at ARB.

Section 2.2.7 page 2-12. The first bullet point indicates that additional runway length will allow for the majority of B-II "small" aircraft to operate without load restrictions. Has it been documented that the current B-II "small" users operate with load restrictions? If so, how often does this occur and what are the quantifiable impacts to their operations?

The third bullet implies that operational safety will be improved with a clear 34:1 approach. Currently the airport has LPV approaches with minimums of 300' and 1 mile. The ADO questions if a flatter approach is warranted in absence of reducing minimums as indicated in the March 4, 2010 e-mail correspondence. The discussion on the 34:1 approach should be re-evaluated and its need clearly identified. Currently the report does not seem to substantiate a need for a 34:1 approach if minimums are not anticipated to be lowered.

Section 3 page 3-1. The report indicates that alternatives were developed to meet the goals of ARB. These goals are to improve safety and efficiency and serve current users. These goals do not appear to be consistent with those previously outlined in the bullet points of section 2.2 (purpose and need). This section should refer to the stated needs and evaluate the alternatives ability to meet those needs.

Section 3.1.3 pages 3-3 and 3-4. There is discussion on extending the runway to the east and a listing of items impacted by pursuing this alternative. There is, however, no conclusion or statement that this option either should be, or was, eliminated. It can be inferred later in the report by the absence of this alternative that it was eliminated but the conclusion as to why it has been eliminated has not been stated.

When addressing the FAA's comments (included within this letter) associated with the stated needs for the project earlier in the report, the responses to these comments may influence the conclusions on why some of the alternatives carried forward have been eliminated. Specifically, if needs stated in section 2.2 are not further substantiated, or it is concluded that one or more of the needs do not exist, additional alternatives may need to be carried forward if they adequately address the needs for the project. The FAA will re-evaluate the conclusions of the alternatives section once the FAA's comments on the purpose and need section are addressed.

Section 3.3 page 3-8. Based on the information presented in the draft EA, the FAA has not reached the same conclusion that alternatives 1 and 2 do not meet the stated needs for the project. An apparent evaluation parameter for alternative 2 included in section 3.3.3 discusses the tower line of sight. This evaluation matrix does not appear to be consistent with those goals stated in Section 3 on page 3-1. The previous comment on the apparent disconnect between the different sections of the report also applies to the specific alternative evaluation. The FAA recommends that the decision matrix for which alternatives were eliminated be clarified in the EA.

Table 3-1 page 3-8. The table appears to incorrectly dismiss alternative 1 because it does not meet purpose and need. .The discussion in 3.3.2 does not support that conclusion. Additionally, there is reference to a future expansion of State Road. This appears to be the first reference to this issue. Is this a need for the State Road expansion project? In what time frame is the State Road expansion project expected to occur? Should there be expanded discussion on other regional planning projects in this EA so the public can better understand the different parameters that ARB is confined to or bound by?

Additional alternatives that may be considered for evaluation to address the need statements could include a combination of items such as: alternative modes of transportation to address enhancing interstate commerce, removal or relocation of obstructions that limit the ATCT line of sight issues, and raising or constructing a new ATCT to address the line of sight issues. Have any previous discussion on additional alternatives been eliminated prior to, or as part of the planning and environmental assessment process for ARB?

Section 3.4 page 3-9. This section contains a brief summary of environmental resources that will not be impacted by build alternative 3. Would it be advantageous to also summarize environmental impacts associated with the other build alternatives? There is a general statement regarding noise impact analysis in this section that identifies that the 65 DNL contour is not within 1,000 feet of any residential structure. What is the purpose for this statement? The FAA is not aware of an environmental impact decision matrix associated with the distance between residential structures and the 65 DNL contour.

Section 4.3.5 page 4-17. The conclusion for the implementation of the preferred alternative states that a positive result of improvements is the ability of business owners to achieve improved fleet efficiency for critical aircraft by maximizing their passenger and/or cargo loads. How has this statement been substantiated? What records exist that current users at ARB are not operating at maximum passenger and/or cargo loads? What has been the economic impact of the reduction of loads if they are occurring?

Section 4.9 pages 4-22 and 4-23. State endangered and special concern species were identified at ARB. The sponsor appears to be proposing a mitigation effort to limit grading for the project to avoid breeding seasons for the specific species. Has this proposed mitigation plan been found to be acceptable by the resource agencies? There is reference to an Audubon Society agreement regarding mowing boundaries. Who is the agreement between? Has this agreement been reviewed by the environmental assessment preparation team? Are there limitations or restrictions for use of airport land as a result of this agreement? Has the Audubon Society been included or have they provided input to this draft EA?

Section 4-15 pages 4-24 and 4-25. The FAA recommends that the score from the USDA form AD 1006 be disclosed in this section and explain what the score means. The consequences identify that some prime and unique farmland of local importance are impacted by this project. The amount of prime and unique farmland should be quantified. Are there any mitigation requirements for this change in use?

Section 4-16 page 4-25. The report identified a decrease in facility energy usage with the installation of LED taxiway lights. Is this net decrease in energy usage compared to baseline or existing conditions?

Section 4.17 page 4-25. There is no discussion on potential relocation of the ODALS or replacement with upgraded equipment. Would there be impacts with either scenario (relocation or replacement)? It should also be noted that the potential exists for the current ODALS to be abandoned if a relocation or upgrade is not justified with a BCA.

Section 4.20 page 4-26. The evaluation regarding construction impacts in the draft EA do not appear to address staging areas during project implementation. The FAA recommends the report verify that staging areas will not impact environmental resources; and as necessary, outline any required mitigation measures for staging area impacts.

Section 4.21 page 4-26. Should the reference to ASTM Standard E1527-94 be updated to E1527-05? The EA should also state if the review was done in accordance with FAA Order 1050.19B, *"Environmental Due Diligence Audits"*.

Section 5 page 5-1. The FAA suggests that this section be titled *Mitigation* rather than *Environmental Consequences – Other Considerations*. We also question if it is prudent to discuss noise, social impacts and community disruption, wetland impacts, and threatened and endangered species in this section since there appear to be no mitigation requirements associated with any of these categories. The FAA suggests either listing all environmental categories reviewed that do not require mitigation or not list any of the categories that do not have required mitigation. Is it a true statement that there are no mitigation measures for threatened and endangered species? Section 4.9 appears to indicate there are seasonal limitations on when grading will occur.

Would it be better to outline required permits for the project in this section, best management practices, construction requirements, etc. rather than having a discussion on what mitigation measures are not required?

Section 6.2.1 pages 6-1 and 6-2. This section includes a summary of when Citizen's Advisory Committee (CAC) meetings were held and the overall agenda for each meeting. The EA does not document either in the text or in an appendix what issues may have been raised and how they were addressed in the CAC meetings. The FAA suggests additional information from the CAC meetings be included in the EA.

Section 6.2.2, page 6-2. The last sentence of this section should indicate that comments received will be reviewed, summarized, and addressed.

Section 7 page 7-3. This section identifies a request that the state and federal agencies approve a Finding of No Significant Impact. This is the first location in the document that specifically requests a federal action. As discussed previously, the FAA requests that earlier in the document the specific actions being requested of each agency be outlined. Based on the review of this document the FAA anticipates that the FAA will be requested to evaluate, and as appropriate, abandon/relocate/replace the existing approach lighting system and develop new flight procedures for the new runway end locations.

Next steps.

The draft EA appears to be intended to be a jointly executed document by both MDOT and the FAA. Since there are several updates/clarifications requested by the FAA contained in this letter and the sponsor's responses may be substantial, it would be prudent to afford the public an additional opportunity to review and comment on the changes that are anticipated to be made for the final draft publication. Most specifically, the document will need to clearly outline the requested local, state and federal actions. Since this was not clearly presented in the initial draft EA, the FAA may consider these changes and clarifications as a material change to the document that should result in solicitation of additional public comment. This may be accomplished by an additional public information meeting or public hearing.

Once the FAA receives confirmation that the above comments have been addressed in the form of an updated draft EA, the FAA requests that we be allotted sufficient time to review, comment, and potentially concur with the updates prior to making the document available to the public for further comment.

If you desire further clarification of these comments, please contact me at (734) 229-2916.

Sincerely,

Brad N. Davidson, P.E.
Community Planner/Environmental Protection Specialist
Detroit Airports District Office

Re: Ann Arbor Municipal Airport (ARB), Environmental Assessment (EA)
Response to Federal Aviation Administration (FAA) Comments

Dear Mr. Gubry:

The Michigan Department of Transportation (MDOT) Bureau of Aeronautics and Freight Services received comments from your office regarding the draft ARB EA dated May 13, 2010. This letter serves as a response to those comments. Please refer to FAA comments shown below in bold text, followed by MDOT responses.

1) **Cover sheet. If the document is to be accepted as a federal document the coversheet will need to reflect this.**

   Response: We were unaware of FAA's current preferred format for cover sheets. Please provide FAA guidance documentation/templates for EA cover sheets. An example of an acceptable cover sheet format would be helpful. We will revise the cover sheet to meet FAA requirements.

2) **Section 2.1. Second bullet states "Shift and extend the parallel taxiway to coincide with the revised Runway 6/24". We recommend revised be changed to extended.**

   Response: Comment acknowledged. This change will be noted in the amended EA.

3) **Section 2.2. This section does not appear to clearly state the need for the proposed action. Are the bulleted "objectives of the proposed project" actually proposed actions? The last bullet states "Relocate and potentially upgrade the Runway 24 Approach Light System". When will it be known if the approach light system will be replaced or upgraded? What is this dependent on? The remainder of the document deals with the impact of the runway extension, but does not address impacts related to the relocation of the existing light system or an upgrade to a new system. Also, action associated with Runway End Identifier Lights (REIL) is**

mentioned later in Section 4.17 and should be listed here as a proposed action. Are there any other NAVAIDs moving or being established?

Response: The bulleted items are considered objectives of the proposed project. The last bullet: "Relocate and potentially upgrade the Runway 24 Approach Light System", was included because the Omni-Directional Approach Lighting System (ODALS) will need to be relocated if the runway is shifted to the southwest, and these lights are very old. Since the ODALS are owned by the FAA, it is the responsibility of the FAA to determine whether the existing lights will be relocated, replaced with the more current MALSF, or abandoned altogether.

There is local preference by the pilots to maintain the ODALS. Since replacing/relocating the ODALS for the shifted runway end does not result in any adverse impacts, the EA conservatively included their relocation. A decision by the FAA that there is no benefit in maintaining them does not result in significant changes to the affected environment described in the EA.

The area of potential effect evaluated in the EA includes the area where the light system would be upgraded and/or relocated. Therefore potential impacts from an upgraded/relocated lighting system have been addressed.

The preferred alternative for a revised Runway 6/24 will result in the relocation and reestablishment of all other associated runway lighting. These lighting systems include Medium Intensity Runway Lights (MIRL), Runway End Identifier Lights (REIL), and Visual Approach Slope Indicator lights (VASI), as well as the Medium Intensity Taxiway Lights (MITL) on the parallel taxiway. These systems are owned and operated by the sponsor and are inherently part of the runway project. They were not called out in the project Purpose and Need, just as the need for new runway paint marking was not called out. Relocation/upgrade of the ODALS was called out specifically in the project justification because this action results in the need for FAA signature on this document. There are no other FAA-owned navigational aids (NAVAIDS) associated with the proposed project.

4) **Section 2.2.1. This section states that the Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF) would serve the same function as the Omni-Directional Approach Lighting System (ODALS) and is structurally very similar. How would the footprint of the MALSF structures compare to the ODALS? What environmental impacts would installation of a MALSF create?**

Response: The footprint of the MALSF would be 100' shorter than the footprint of the existing ODALS.

The MALSF consists of seven light structures, all of which are located on the extended runway centerline. The structures are located with a 200' spacing between each, for a total overall length of 1,400'.

The ODALS consist of five light structures located on the extended runway centerline, with a 300' spacing between each structure, for a total overall length of 1,500'. Two additional ground-level light fixtures are located at the runway threshold, one on each side.

Additional details regarding MALSF and ODALS approach light systems are included in FAA Advisory Circular 150/5340-30D. Installation of the MALSF will not result in any adverse environmental impacts, as identified in Section 4.17.

5) **Section 3.1.2. We suggest adding a qualifier in the second paragraph to state the following: "…would be greater than those expected with the proposed expansion of ARB in its current location."**

Response: Comment acknowledged. This change will be noted in the amended EA.

6) **Section 4.4. The Consequences of the Preferred Alternative section states: "Comparisons of existing conditions at various airports with future build out conditions indicate that the net change in air emission is still below standards." Do these conditions include runway extension projects similar to the proposed action at ARB?**

Response: The conditions referenced in this section are based on the comparison of operational emission rates of seven case study airports across the state. The case studies, which included airports similar to ARB, did evaluate the operational emission rates of the airports in their proposed ultimate build out conditions.

Project construction emission rates are estimated to be less than eight tons per year of NOx, well below the Environmental Protection Agencies de minimis threshold of 100 tons/year (rates derived from US Court of Appeals Case, City of Olmstead Falls v. FAA, 2002). Therefore, the emissions do not constitute a change in conditions for the proposed ARB runway extension project.

7) **This section additionally states: "Consequently, the air model results for the Preferred Alternative would be identical to those for the No Build Condition." This statement implies that no air emissions would result from the proposed action. Is this accurate?**

Response: As stated in this section of the draft EA, the Air Quality Study conducted by Landrum and Brown concluded that proposed projects at general aviation airports are not expected to cause or contribute to any new violations of the National Ambient Air Quality Standards (NAAQS). Also, the results of the air model analysis showed that net aircraft emissions are not expected to increase as a result of the proposed project. Therefore, aircraft emissions should be the same - with or without the project.

Additionally, a model was run to determine automotive-related emissions associated with the proposed project. Since there would be no revisions to the existing roadway system as a result of the project, the model showed that there would be no increase in air emissions attributed to automobiles.

8) **Section 4.5.1. Would the existing Storm Water Pollution Prevention Program cover the additional impervious surface area?**

Response: Yes

9) **Section 4.5.2. We would recommend rewording the first sentence of the Consequences of the Preferred Alternative section to the following (if true and appropriate): Surface and subsurface geological conditions would not be impacted by the Preferred Alternative.**

Response: Comment acknowledged. This change will be noted in the amended EA.

Flight Procedures offers the following comments:

10) **No comments were provided by Flight Procedures Office (FPO).**

11) **However, it should be noted that the FPO must be notified by formal letter to request the development of future approach procedures for the relocated runway end coordinates. Information needed includes identification of when construction will start, finish, when the equipment will be relocated, etc. This information is critical for developing/amending approach procedures. The FPO must know the project phasing in order to have procedures ready when construction is complete. (Equipment relocation, threshold displacements, etc). Changes in runway pavement length will result in survey data. Please note that survey data must meet the specifications outlined in Advisory Circulars 150/5300-16, 17, and 18. Third party surveys must be coordinated with the FPO. The proponent must submit Proposed Equipment Relocation Data along with information related to any equipment that will be relocated or added to AVN-210 and ATA-110. 7. Publication of new/amended Approach Procedures could take from 18 months to 2 years after runway data is submitted to AVN-210 and ATA-110. NOTE: Development of Approach Procedures will not begin until an official letter of request for development of procedures is received by FPO and the proposed runway data and equipment data provided to AVN-210 and ATA-110. Proponent must update the airport FAA Form 5010-1 to reflect new runway data and updated runway changes.**

Response: Comments acknowledged

Airports Division offers the following comments:

12) **The report is not clear if there is a federal action being requested.**

Response: The format of the draft EA is the same format used for other EA's co-signed by MDOT and FAA under the block grant agreement. The FAA was involved with this project since it began and understands the proposed actions. That said, we acknowledge the document does not explicitly state the 'proposed federal action'. We suggest that previous FAA/MDOT actions have included this information in the Finding of No Significant Impact (FONSI) document and that we use the same approach with this project.

13) **Based on the information contained within the draft EA it appears that at least two federal actions are being requested. These actions include the relocation or replacement of the current approach lighting system as well as the development for future approach procedures for the new runway end locations. The FAA recommends that these actions be clearly identified throughout the document. The first page of the document states that this draft EA will become a State of Michigan document when signed by the State Official and does not include similar language for the Federal Aviation Administration although there is a signature line included for a federal official. Please refer to FAA Order 5050.4B section 707(f).**

Response: As stated above, the requested federal action is relocation or abandonment of the federally owned NAVAIDs (ODALS). MDOT has never included development of a new approach as a stated action in an EA. To date, FAA Flight Procedures Office has always completed separate environmental clearance for new approaches. We request clarification from FAA that this is necessary and suggest that development of a new approach is inherent as part of the proposed runway shift/extension (e.g. like paint marking) and should not have to be called out as a separate proposed action.

14) **Section 1 page 1-1. The draft EA states that the projects under consideration are those shown on the FAA approved Airport Layout Plan (ALP). This statement should be clarified as to the role of Michigan Department of Transportation (MDOT) in conditionally approving the ALP set on behalf of the FAA under the authority of the State Block Grant Program. When referencing the ALP throughout the document, additional emphasis should be made to the June 23, 2008 ALP approval letter that clearly states that the approval is conditional. Several conditions were placed on the approval letter including the requirements that the projects contained within the ALP set must comply with the National Environmental Policy Act (NEPA). The FAA recommends inclusion of the conditional ALP approval letter in the draft EA for disclosure purposes.**

Response: The standard language that is used in the ALP approval letters for all FAA-NPIAS airports is that they are "conditionally approved", subject to environmental clearances, justification for development of specific projects, etc.

This language was originally developed by the FAA back when that agency was responsible for signing the ALP approval letters. When MDOT became a block grant state and took over the responsibility of signing the ALP approval letters on behalf of the

FAA, we kept the same boilerplate language that the FAA had been using, and referred to all approvals as "conditional approvals".

Although the standard language in the approval letter for the April 2008 ALP for Ann Arbor Municipal Airport states that it has been "conditionally approved" by MDOT, it is in fact a fully-approved ALP, the same as any other airport with an approved ALP. The ALP was reviewed by many branches of the FAA through the customary FAA-Airspace Review process, and all FAA comments or concerns were addressed prior to MDOT signing the standard format approval letter on behalf of the FAA.

Paragraph No. 1 of the ALP approval letter specifically states that the FAA has concurred with the proposed development on the ALP for planning purposes based on current safety, utility, and efficiency standards, with the condition that justification of need is required prior to seeking FAA financial participation in the actual development of the projects.

Since the ALP has in fact been thoroughly reviewed and approved by both the FAA and MDOT, we do not agree that when referencing the current approved ALP in the EA, there is a need to specify that it is "only conditionally approved by MDOT". Stating such would be misleading, as it infers that the ALP does not have FAA approval, and only a limited approval by MDOT.

ALP approval letters have never been a part of any of our past EAs, and there are no established procedures which require or recommend the inclusion of such. If the FAA would like to discuss a change in policy regarding inclusion of ALP approval letters in all future EAs, we are open to further discussion.

15) **We also suggest the executive summary clearly outline who will be responsible for actions associated with the proposed project (i.e. local sponsor, local unit of government, State of Michigan, Federal Government). For the FAA to co-sign the document, the requested Federal Actions must be clearly identified within the executive summary and throughout the document where appropriate.**

Response: The format of the draft EA is the same format used for other EA's co-signed by MDOT and FAA under the block grant agreement. The FAA was involved with this project since it began and understands the proposed actions. That being said, we acknowledge the document does not explicitly state the 'proposed federal action'. We suggest that previous FAA/MDOT actions have included this information in the FONSI document and that we use the same approach with this project.

16) **Section 2 page 2-1. References to the ALP set need to clarify that MDOT has only conditionally approved the ALP.**

Response: See response to comment 14.

17) **Section 2.2 page 2-4. The classification of a B-II Small Aircraft has been determined with a reference to MDOT 2009. Is the B-II "Small Aircraft" a designation that is contained within MDOT planning guidance? The FAA is not familiar with the classification of "small" when identifying the critical design aircraft for an airport. Please clarify how this distinction was derived.**

Response: In the User Survey Report, reference is made to FAA Advisory Circular 150/5325-4B "*Runway Length Requirements for Airport Design*". In this AC, the FAA has published guidance and runway length curves for family groupings of airplanes with similar performance characteristics and operating weights.

Chapter 2 of the AC provides FAA runway length recommendations and runway length curves for "Small Airplanes with Maximum Certificated Takeoff Weight of 12,500 Pounds or Less". Chapter 3 provides FAA guidance and runway length curves for "Airplanes with Maximum Certificated Takeoff Weight of More Than 12,500 Pounds Up To and Including 60,000 Pounds" (Large Airplanes).

In order to determine which chapter of the FAA AC was applicable to ARB, the weight classification of the critical aircraft family had to first be identified. The user survey analysis confirmed that the family grouping of airplanes that were included in the B-II critical aircraft category were of the "small" aircraft weight classification. Therefore, the runway length curves from Chapter 2 of the AC were referenced in the User Survey Report in the discussion regarding runway length recommendations. Use of the runway length curves from Chapter 3 would have resulted in longer runway length recommendations.

The critical aircraft weight category analysis was conducted solely for the purpose of referencing FAA AC 150/5325-4B. MDOT planning guidance regarding runway length recommendations does not distinguish between weight categories. The critical aircraft category as listed on the current approved ALP is "B-II". No reference is made to the small or large weight category.

18) **Section 2.2 page 2-4. The paragraph discussing Origin-Destination Analysis should be expanded (or references made where information can be reviewed) to provide clarification to the general statements that are made. Specifically, is there a list of destinations that can be provided that will substantiate the need for a runway extension? A listing of destinations may aid the reader in putting the proposed project into perspective and may further substantiate the need for a runway extension. The report states that a significant number of operations occur between ARB and distant locations without quantifying the number and types of operations that are being referenced. The FAA recommends this be clarified in the report or referenced to the appropriate appendices.**

Response: Additional Origin-Destination information, including a list of 32 states and numbers of operations between ARB and each state, is included in Exhibit No. 2 of the Supplemental Report to the Airport User Survey. The Supplemental Report is included in Appendix A-2 of the draft EA, which was reviewed by your office. We will add a note to the amended EA referencing Appendix A-2 for additional information.

19) Section 2.2 page 2-5. Are the bulleted items for the objectives of the proposed project presented in order of relative importance?

Response: No, it is simply a list of objectives for the proposed project.

20) The statement that the project will enhance interstate commerce does not appear to be substantiated by supporting documentation here or elsewhere in the document. How has this been verified? What are the enhancements? Is this a need for the project? The FAA recommends referring to FAA Orders and Advisory Circulars that address runway length, operational capacity of the aircraft utilizing ARB, and any deficiencies that currently exist at ARB that are a function of the current runway length. Without a detailed discussion and explanation of what the interstate commerce enhancement is and how this has been quantified as a current need, the FAA does not recognize this as a need for the project based on the information provided.

Response: The need for the project is not based on the enhancement of interstate commerce. Therefore, there is no documentation provided in the EA to substantiate that position. The need for the project is based on the objective of providing a primary runway of suitable length to safely accommodate critical category aircraft without operational weight restrictions.

Section 2.2 (Purpose and Need) and Appendix A (User Survey Reports) of the EA explain in detail the purpose, need, and justification for the project. FAA Advisory Circular 150/5325-4B "*Runway Length Requirements for Airport Design*" and the Michigan Airport System Plan (MASP) airport development standards were referenced in determining project justification and proposed runway length.

Enhancement of interstate commerce is a benefit of providing a runway long enough to avoid weight restrictions on critical aircraft. If business aircraft have to fly with restricted loads of passengers and/or cargo, there are obviously negative financial impacts to the operators. Such cases may result in an operator having to use two separate aircraft when one operated at its full capacity would have been sufficient to accomplish the objective. Also, if business aircraft have to fly with restricted fuel loads, the operators potentially would have to make interim fuel stops prior to reaching their destinations. Additional fuel stops result in time delays and additional operational expenses.

The final EA will clarify that the enhancement of interstate commerce is not a project objective or need, but rather a benefit of the proposed project.

21) If enhancing interstate commerce is a stated need for the project then the report should be expanded to include a full range of alternatives that can address this need including alternative modes of transportation as an example.

Response: As stated above, the enhancement of interstate commerce is not a stated need for the project, but rather an obvious benefit of the project. The airport serves aircraft that are being used for interstate commerce. Provision of a runway of sufficient length to allow critical category aircraft to operate without weight restrictions is a stated objective of the project.

22) **The last bulleted objective in this section is for the relocation and potential upgrade of the Runway 24 approach lighting system. The report does not appear to document why this is a need for the project or if the approach lighting system is currently required or needed in the future.**

Response: See response to comment 3.

23) **What benefit does the current approach lighting system provide the airport? There does not appear to be a credit for a reduction in minimums at the airport as a result of having the ODALS. Has a Benefit Cost Analysis (BCA) been completed or requested of the FAA substantiating the need for relocating or replacing the ODALS? Depending on the results of the BCA and associated justification for relocating the existing or installing a replacement light lane at ARB, the potential exists that the Federal Action may be limited to abandoning the existing ODALS and no relocation or replacement would occur with federal funds.**

Response: A BCA has not been completed at this time. Please see response to comment 3.

24) **Section 2.2.1 page 2-5. The first paragraph implies that runway incursions have been occurring at ARB as a result of issues with the current line of sight between the ATCT and a portion of the taxiway system and taxiway hold area. The report further indicates that the proposed project will possibly prevent incursions from occurring. Are there any documented runway incursions resulting from the current line of sight issue that can be included in the report to substantiate this claim? The FAA supports safety enhancement projects and would consider this a measure to improve the line of sight from the ATCT to parallel taxiway and the hold area if it can be demonstrated that the existing condition contributes to runway incursions. While a goal of the FAA is to reduce the number of runway incursions at airports nationwide, the FAA can not definitively conclude that this proposed safety enhancement at ARB will potentially prevent runway incursions but rather if the line of sight issue is improved this may reduce the possibility of runway incursions.**

Response: The first paragraph does not imply that runway incursions have been occurring at ARB as a result of ATCT line-of-sight issues. It merely states that the proposed threshold shift would "enhance operational safety" and "possibly prevent a runway incursion by expanding the view of the hold area and parallel taxiway to ATCT personnel". Certainly if the threshold shift "may reduce the possibility of runway incursions" as stated in your comment, then it would also "possibly prevent a runway incursion" from taking place.

The main point is that ATCT personnel do not have a clear view of the taxiway end and hold line area. The obstructed view restricts their ability to clearly see taxiing or holding aircraft and their N-numbers, and increases the possibility of runway incursion due to either pilot or controller error. While we are not aware of any incursions that have occurred as a result of this condition, we believe it is appropriate to address the condition while the runway extension is being considered.

Mr. Charles Smith, ATCT Manager at ARB, has expressed his concern over the non-visibility area and potential for runway incursion. He has stated in written correspondence to our office "I believe that the potential for an event is very real".

We are unclear why the FAA questions the justification of this safety enhancement measure when it obviously improves the existing condition and it is supported by ATCT management and staff. Does the FAA need records of adverse events that have actually occurred before they agree that there is justification to address a less than optimal situation?

MDOT would rather be proactive in enhancing the safety of this situation prior to a potentially catastrophic runway incursion taking place, rather than waiting for one to take place just for the record, and be reactive to it afterwards. We repeat neither the extension nor the shift result in measurable adverse impacts to the environment or surrounding communities.

25) **This section includes discussion of the potential to achieve a clear 34:1 approach and reduce minimums at the airport. The ADO previously requested clarification on this issue in an e-mail dated March 4, 2010 (attached for reference). Based on the e-mail exchange, the FAA understands there is no anticipation of a reducing of minimums at this airport for the foreseeable planning future.**

Response: Comment acknowledged. Additional clarification regarding the 34:1 approach surface will be provided in the amended EA.

26) **Since minimums will not be reduced as a result of the project, the FAA is unclear on the need for a 34:1 approach or how it enhances safety of the approach procedures currently published for the airport based on the existing 20:1 approaches. The document should better explain how providing a 34:1 approach enhances safety for the existing and future users at the airport or how this also may impact interstate commerce. Has the current 20:1 clear approach resulted in missed approaches that have been documented? If so how often does this condition occur?**

Response: There is currently not a "need" for the 34:1 approach. However, shifting the runway threshold to eliminate the ATCT line-of-sight concerns does result in the provision of a clear 34:1 surface to the relocated threshold.

As stated in the EA, with obstacles in the approach area remaining below the flatter 34:1 surface (as opposed to the existing steeper 20:1 surface), an additional margin of safety is provided between approaching aircraft and ground-based obstacles. This is particularly beneficial in low-visibility conditions, such as when aircraft are operating at night or in fog, rain, or snow.

If an aircraft is making an approach to a runway in conditions with poor visibility of the airport environment (either IFR or night VFR), and the pilot unwittingly drops below the intended glide path, there is the potential for the aircraft to strike an unseen obstacle in the approach area. Since a clear 34:1 approach surface provides a greater vertical distance between the aircraft and the obstacles than the clear 20:1 surface provides, the aircraft is less likely to collide with the unseen obstacles. It is obvious that an additional margin of safety is provided by a clear 34:1 approach surface, even though it is not required and it is not the reason for the proposed threshold relocation.

The EA stated that interstate commerce would be enhanced if the all-weather capability of the airport was improved by lowering visibility minimums of the Instrument Approach Procedure from the current 1-mile minimum to ¾-mile minimum. This would allow the airport to remain open for flight activity when the visibility dropped below 1-mile, thereby allowing for the continuation of business and interstate commerce. The EA did not say that the threshold shift, or providing for a 34:1 approach surface, would enhance interstate commerce.

Since we agreed to remove reference to the potential of a future ¾-mile visibility minimum Instrument Approach Procedure from the draft EA document (as stated in our response to the ADO e-mail dated March 4, 2010), we will also remove reference to the fact that interstate commerce would be enhanced by a ¾-mile approach procedure. Statements of clarification will be added to the amended EA.

Missed approaches are the result of pilots not being able to visually detect the airport environment well enough to complete the final phase of landing visually, upon reaching the published Minimum Descent Altitude of the Instrument Approach Procedure. They are unrelated to a clear 20:1 approach surface versus a clear 34:1 approach surface. Therefore, the current 20:1 approach surface has not resulted in missed approaches, documented or otherwise.

27) **Is providing clear 34:1 approaches a project need or a benefit that may result from the relocation of the runway? Earlier in the report it was identified as a stated objective, however, the discussion in the report does not appear to substantiate the need for this when combined with the e-mail exchange of March 4, 2010 and conditionally approved ALP dated June 23, 2008.**

Response: As previously stated, a clear 34:1 approach is not a project need, but it is a benefit that results from the relocation of the Runway 24 threshold. The threshold is not proposed to be relocated in order to provide for a clear 34:1 approach surface, but rather to enhance safety by eliminating the ATCT line-of-sight and non-visibility concerns.

28) While the future 34:1 approaches are identified on the conditionally approved ALP, it should be noted that this would result in an expansion of the approach surface from the existing 500'x2,000'x5,000' to 500'x3,500'x10,000'. The EA needs to fully disclose the increase in the approach surface if a 34:1 approach is achieved and document any environmental impacts that result from the larger approach surface.

Response: The achievement of a clear 34:1 approach surface is a byproduct of the proposed shift of the Runway 24 threshold for ATCT visibility purposes. The proposed project does not require a clear 34:1 approach surface, nor does it require any other 34:1 approach surface standards, including the application of the expanded approach surface dimensions. Therefore, discussion regarding environmental impacts that are associated with a larger approach surface are not included in the EA.

29) Section 2.2.2 page 2-6. It is not clear to the FAA why there is a summary of Wings of Mercy operations since 1992 including 51 flights reported in 2009. This data appears to be in addition to what was collected as part of the user survey report that relied predominately on information from calendar year 2007. What is the relevance of including the 2009 data or specifically identifying the Wings of Mercy flight operations? Are there a range of aircraft types that fly for Wings of Mercy? Does the proposed runway extension impact their operational capacity?

Response: This information was requested by FAA staff and it is intended to describe the nature of operations at the airport.

30) Section 2.2.2 page 2-7. Discussion on the Michigan State System Plan (MASP) identifies the airport reference code (ARC) as B-II. Does the MASP differentiate between B-II small and B-II large? In absence of a clearly defined category of B-II "small aircraft", the FAA would suggest simply referring to the airport with a B-II ARC.

Response: The MASP does not differentiate between B-II small and B-II large. Tables 40 and 41 of the MASP show that for the B-II airport classification as a whole, a primary runway length of 4,300' is an airport development standard throughout the state of Michigan. The ARC as listed on the current ALP is B-II, with no reference to either the small or large category. As stated earlier in this document, the reason that the small and large weight classifications were defined during the identification of the critical aircraft category was solely for the purpose of referencing the runway length recommendations contained within FAA AC 150/5325-4B.

31) Section 2.2.3 pages 2-7 and 2-8. This section most clearly identifies why a runway extension is being proposed in accordance with FAA advisory circulars and State standards outlined in the 2008 MASP. This section, in combination with section 2.2.4 that documents substantial use (i.e. over 500 annual operations) by the B-II

critical design family of aircraft appears to substantiate the justification for the runway extension based on the 2007 operational data.

Response: Comment acknowledged. Justification for the project is also substantiated by analysis of year 2009 operational data – the most current available. The updated analysis will be included in the amended EA.

32) **Section 2.2.4 page 2-9. Detailed operational information is presented for calendar year 2007. Subsequent years are generalized based on trend analysis and overall decrease in operations as reported in the FAA Terminal Area Forecast (TAF). There does not appear to be an evaluation to account for the 21.8% decrease in operations between 2007 and 2009. Would it be prudent to verify if the operational decrease impacted one user group more than other user groups? Are the numbers of local and itinerant operations decreasing at the same rate or is one segment impacted to a greater extent? This evaluation may be accomplished through additional user survey data collection or potentially from the ATCT located at ARB for subsequent years since 2007. Additionally, the FAA recommends that the year of the TAF being utilized for this report be identified.**

Response: Additional user survey data for calendar year 2009 has been collected and analyzed. This is the most up-to-date operational data available. Full details are included in the *Year 2009 Operational Data Analysis*. This report will be included in the amended EA.

The FAA TAF forecasted a 21.8% decrease in operations at ARB from years 2007 through 2009. Analysis of the actual year 2009 operational data later confirmed that even with the forecasted decrease in operations, there were still over 500 annual itinerant operations conducted by category B-II aircraft at ARB in 2009. Therefore, the current critical aircraft category has been substantiated as B-II.

The FAA TAF report that was referred to in the EA was obtained from the FAA database on July 2, 2009. During the most recent update of the user survey (Year 2009 Operational Data Analysis), an updated TAF was obtained from the FAA database on August 26, 2010 (forecasts issued December 2009). This most current version of the TAF projects itinerant operations at ARB to reverse the recent downward trend, and continually increase from years 2010 through 2030. A copy of this TAF will be included in the amended EA.

33) **Section 2.2.4 page 2-11. Specific information for AvFuel Corporation is presented to validate assumptions for the continued classification of the airport as B-II. It should be noted that AvFuel bases a Citation 560 Excel jet at ARB and is designated in the report as a B-II "Large" aircraft. The discussion further indicates that the Chief Pilot submitted written documentation regarding potential future operational levels at ARB. The written documentation does not appear to be included within the report or appendices. However, according to the text in the report, the Chief Pilot anticipates future operational levels increasing to 350-450 annual operations.**

This level of use, in combination with a limited number of additional similar B-II aircraft would appear to classify the airport as a B-II "Large" designation. The FAA reiterates the hesitation on identification of either a "small" or "large" within an airport reference code and recommends that any qualifier to the size of the B-II critical design aircraft be removed from the report. The number of operations forecasted to occur by AvFuel Corporation would further support the elimination of the qualifier as "small" to the ARC.

Response: It is noted in both the December 2009 Supplemental Report and the September 2010 update to the airport user survey (Year 2009 Operational Data Analysis) that AvFuel Corporation bases a B-II large category Citation 560 Excel jet at ARB. The December 2009 report was included in Appendix A-2 of the draft EA that was reviewed by your office.

Letters from AvFuel's Chief Pilot, which provide operational information for their Citation 560 Excel jet, are included in the September 2010 update to the airport user survey. This update will be included in the amended EA.

As mentioned in earlier responses, the user survey analysis distinguished between small and large category aircraft in order to determine the appropriate runway length guidance from FAA AC 150/5325-4B. The Airport Reference Code as shown on the ALP is B-II, with no reference to the small or large category.

34) **Section 2.2.6 page 2-12. The local objective of reducing runway overrun incidents appears to conclude that if the added runway length were present, all the incidents would have been avoided. Based on information presented, the FAA does not necessarily come to the same conclusion. There are many factors that go into any overrun incident and if additional runway length were present this may have only prolonged the overrun incident. The A-I category of aircraft involved with overrun incidents do not appear to have needed any length beyond the existing runway length to operate at full capacity and in a safe manner.**

Response: The vast majority, if not all, of the A-I category of aircraft that utilize ARB (including those involved with overrun incidents) do not need additional runway length to operate at full capacity and in a safe manner. Justification for the proposed runway extension was based solely on operational levels and needs by the more demanding category B-II aircraft.

Reduction of runway overrun incidents is clearly stated in the EA as a local objective, and it is not recognized by the FAA or MDOT as providing justification for the proposed runway extension. However, there is merit to the local objective, as the runway extension would in fact provide additional pavement for landing rollout for the small category A-I aircraft, and thereby reduce the potential for this category of aircraft to roll off the runway end into the turf Runway Safety Area.

35) **The paragraph that references Accelerated Stop Distance Available (ASDA) requirements appear to include fleet mixes other than A-I and implies that aircraft can accommodate their operational requirements with a reduced load capacity. The ADO is not aware of any A-I aircraft operating at ARB that would need to operate at a reduced load capacity to adequately satisfy their calculations for safely operating at ARB.**

Response: We are also unaware of any A-I category aircraft operating at ARB that would need to operate at reduced load capacity to adequately satisfy their calculations for safely operating at ARB. And yes, the larger category aircraft, including the B-II category critical aircraft, can safely accommodate accelerate-stop distance requirements at ARB with a reduced load capacity.

However, as stated in FAA AC 150/5325-4B, *"The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions"*. As clearly stated in the EA, the main objective of the proposed project is to provide a primary runway of sufficient length to allow the B-II critical aircraft family to operate without weight restrictions.

The point of your comment is unclear.

36) **It is not clear when the 11 overrun incidents occurred, their cause, or conclusions that support that runway length was a factor in the overrun incidents. Can additional information be provided to support this position? If additional information is not available the FAA recommends removing this section from the document.**

Response: Lack of suitable runway length was not a causal factor in the overrun incidents. Pilot error and mechanical problems with aircraft brakes were the factors indicated in the incident reports that resulted in the aircraft overrunning the runway end.

As previously stated, the justification for the extension of Runway 6/24 is based solely on the operational levels and requirements of category B-II critical aircraft. The local objective of reducing runway overruns is not recognized by existing MDOT or FAA standards as providing justification for the runway extension, and therefore it was mentioned in the "Other Considerations" section of the EA. Since this local objective does not technically generate justification for the runway extension from the state or federal perspective, there was no related in-depth information provided in the EA to substantiate the local perspective.

37) **The FAA recognizes that this section of the report was included as a local objective and it is clearly and appropriately stated that the FAA does not recognize this as a need for extending the runway at ARB.**

Response: Comment acknowledged.

38) **Section 2.2.7 page 2-12. The first bullet point indicates that additional runway length will allow for the majority of B-II "small" aircraft to operate without load restrictions. Has it been documented that the current B-II "small" users operate with load restrictions? If so, how often does this occur and what are the quantifiable impacts to their operations?**

Response: According to FAA AC 150/5325-4B, *"Runway Length Requirements for Airport Design"*, when the maximum certificated takeoff weight (MTOW) of critical category airplanes is 60,000 lbs. or less, the recommended runway length is determined according to a *family grouping of airplanes* having similar performance characteristics and operating weights. When the MTOW of critical category airplanes exceeds 60,000 lbs., the recommended runway length is determined according to *individual airplanes*.

Since the user survey confirmed that the current critical aircraft category at ARB is B-II small aircraft (12,500 lbs. or less), Figure 2-2 of the AC and Table 40 of the MASP were referenced in the determination of the recommended runway length of 4,300'. The runway length curves shown in Figure 2-2 of the AC were developed by the FAA for a family grouping of airplanes with similar performance characteristics and operating weights. As noted in the AC, the FAA considered takeoff, landing, and accelerate-stop distance requirements of the family grouping in the development of the runway length curves.

It has not been documented that all current B-II small aircraft operate with load restrictions at ARB, since we do not have information specific to the performance characteristics and corporate operating policies of every B-II category aircraft. However, as a means of confirming the accuracy and relevancy of the runway length curves developed for the family grouping of aircraft depicted in Figure 2-2 of the AC, an analysis was conducted using the individual airplane flight manual from the State of Michigan's Beechcraft King Air 200.

This airplane model is a very common B-II small category corporate aircraft, many of which currently operate at ARB. It is also a representative airplane of the family grouping of aircraft included in Figure 2-2. Analysis of the flight manual confirmed that this aircraft would indeed have to operate with load restrictions at ARB on an 83 degree F design day on the existing 3,505' runway. The analysis also confirmed that this same airplane could operate without load restrictions in the same conditions on the proposed 4,300' runway.

As stated on the title page of the FAA AC, "For airport projects receiving federal funding, the use of this AC is mandatory". The runway length curves contained within were developed based on the FAA objective of providing a runway of sufficient length to allow the critical aircraft family to operate without weight restrictions. The proposed project would achieve the FAA objective and benefit the family grouping as a whole by allowing for the majority, if not all, of B-II small category aircraft to operate without load restrictions.

The determination of quantifiable impacts of load restrictions is beyond the scope of the user survey process, and such highly detailed information is typically not used in the determination of justification for runway extensions. The benefits or requirements to perform such a study are also not discussed anywhere in the FAA AC regarding runway length requirements.

39) **The third bullet implies that operational safety will be improved with a clear 34:1 approach. Currently the airport has LPV approaches with minimums of 300' and 1 mile. The ADO questions if a flatter approach is warranted in absence of reducing minimums as indicated in the March 4, 2010 e-mail correspondence. The discussion on the 34:1 approach should be re-evaluated and its need clearly identified. Currently the report does not seem to substantiate a need for a 34:1 approach if minimums are not anticipated to be lowered.**

Response: As previously stated, there is not a "need" for a 34:1 approach. Rather, shifting the runway 24 threshold to eliminate the ATCT line-of-sight concerns results in the provision of a clear 34:1 surface to the relocated threshold. Additional clarification regarding the 34:1 approach surface will be provided in the amended EA.

40) **Section 3 page 3-1. The report indicates that alternatives were developed to meet the goals of ARB. These goals are to improve safety and efficiency and serve current users. These goals do not appear to be consistent with those previously outlined in the bullet points of section 2.2 (purpose and need). This section should refer to the stated needs and evaluate the alternatives ability to meet those needs.**

Response: The introductory paragraph to section 3 was intended to summarize project purpose and need as a means of introducing the alternatives considered. While the objectives previously stated in the project Purpose and Need of section 2 are not stated verbatim here, we believe "improve safety and efficiency, and serve current users" is sufficient summary.

41) **Section 3.1.3 pages 3-3 and 3-4. There is discussion on extending the runway to the east and a listing of items impacted by pursuing this alternative. There is, however, no conclusion or statement that this option either should be, or was, eliminated. It can be inferred later in the report by the absence of this alternative that it was eliminated but the conclusion as to why it has been eliminated has not been stated.**

Response: The last sentence in section 3.1.3 should have stated that this alternative was dismissed and why. Specifically, it should have stated "this alternative was dismissed because it is not compatible with local plans and due to the extent of safety, transportation and wetland impacts from relocating State Road". This sentence will be added to the amended EA.

42) **When addressing the FAA's comments (included within this letter) associated with the stated needs for the project earlier in the report, the responses to these comments may influence the conclusions on why some of the alternatives carried**

forward have been eliminated. Specifically, if needs stated in section 2.2 are not further substantiated, or it is concluded that one or more of the needs do not exist, additional alternatives may need to be carried forward if they adequately address the needs for the project. The FAA will re-evaluate the conclusions of the alternatives section once the FAA's comments on the purpose and need section are addressed.

Response: Comment acknowledged.

43) Section 3.3 page 3-8. Based on the information presented in the draft EA, the FAA has not reached the same conclusion that alternatives 1 and 2 do not meet the stated needs for the project. An apparent evaluation parameter for alternative 2 included in section 3.3.3 discusses the tower line of sight. This evaluation matrix does not appear to be consistent with those goals stated in Section 3 on page 3-1. The previous comment on the apparent disconnect between the different sections of the report also applies to the specific alternative evaluation. The FAA recommends that the decision matrix for which alternatives were eliminated be clarified in the EA.

Response: See responses to comments 24 and 40. This comment appears related to the need for addressing the ATCT line-of-sight issue and the need for the shift of the Runway 24 threshold.

44) Table 3-1 page 3-8. The table appears to incorrectly dismiss alternative 1 because it does not meet purpose and need. The discussion in 3.3.2 does not support that conclusion. Additionally, there is reference to a future expansion of State Road. This appears to be the first reference to this issue. Is this a need for the State Road expansion project? In what time frame is the State Road expansion project expected to occur? Should there be expanded discussion on other regional planning projects in this EA so the public can better understand the different parameters that ARB is confined to or bound by?

Response: Alternative 1 was considered because it moves the approach south of the Stonebridge neighborhood. It would result in measurable adverse environmental impacts including wetland fill, stream impacts and tree clearing. The rational for dismissal of this alternative indicated in 3.3.2 is valid. We agree that it would meet the project purpose and need and a revised Table 3-1 will be included in the amended EA.

Any future widening of State Road, as recommended in the 2006 State Road Corridor Study, would be completely independent of the proposed airport project. We do not know when, or even if, the Washtenaw County Road Commission proposes to widen State Road. As previously stated, the justification for the proposed shift of the Runway 24 threshold is to resolve ATCT line-of-sight issues. The provision of additional room to widen State Road would be a secondary benefit of the shift, but it is not a driving reason for the shift.

it's like being there

City Council Acts on Zoning, Airport, Streets

Also: Residents raise concerns over flooding, DTE "smart meters"

BY DAVE ASKINS APRIL 21, 2012 at 6 pm

Ann Arbor city council meeting (April 16, 2012): The most significant item on the council's agenda was the introduction of the city's proposed fiscal year 2013 budget by city administrator Steve Powers.

But Powers led off the presentation by explaining that Monday evening would not be a time for detailed discussion and questions about the budget. For details of that presentation, see Chronicle coverage: "Ann Arbor Council Gets Draft 2013 Budget."

WEMU's Andrew Cluley had questions about the budget for Ann Arbor city administrator Steve Powers after the April 16 council meeting. Image links to Cluley's report. (Photos by the writer.)

The budget presentation occurred Monday night because of a city charter requirement. It was Powers' first such presentation – as he was hired by the council last year, and started the job in September. The city council will have until May 21, its second meeting in May, to modify and adopt the budget.

In terms of the sheer number of agenda items, the topic of zoning and land use was a main focus of the meeting. The council unanimously rejected a proposed conditional rezoning of 1320 S. University to a higher density than its current D2 (downtown interface) designation. But winning unanimous approval was a site plan for a Tim Hortons on South State Street, near Ellsworth. The council also gave initial approval to AAA Michigan for a rezoning request involving a parcel on South Main, which the auto club would like to have designated as P (parking). A half dozen different rezoning requests for parcels that had recently been annexed into the city also received initial approval.

Prompting considerable discussion among councilmembers were four resolutions concerning an environmental study on a possible extension of a runway at the Ann Arbor municipal airport. The resolutions all passed, but the main grant funding went through on just a 7-4 vote. The city was being asked for an additional $1,125 in matching funds to wrap up the final stages of an environmental assessment being done by the Michigan Dept. of Transportation, which was already mostly completed two years ago.

Also related to transportation, the council authorized over $6 million in contracts related to street resurfacing projects. That included a second set of local streets (after having approved funding for the first set at its previous meeting) as well as the section of East Stadium Boulevard between Packard and Washtenaw. In connection with those infrastructure projects, the council also authorized contracts for materials testing.

In other action related to infrastructure, the council approved a $93,438 item for construction of unisex bathrooms in city hall – but not without questions about the scope of the overall municipal center renovation work.

On personnel-related items, the council gave final approval to legislation that incorporates provisions of the collectively bargained labor contracts with police command officers and firefighters into the city's set of ordinances on retirement and health care.

As a result of other council action on Monday night, Ann Arbor police officers will be able to arrest and charge "super drunk" drivers who have more than 0.17 blood alcohol content – because the council modified the city's ordinances to conform with recent changes in state law.

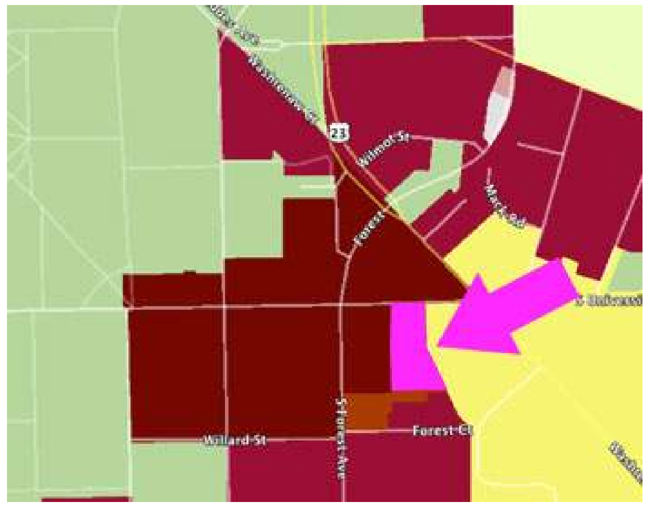
In other business, the council also authorized a contract with a new auditor, The Rehmann Group, set a hearing on a tax abatement for Sakti3, and imposed a temporary ban on digital billboards.

Highlights of public commentary included concerns about new DTE "smart meters" and localized flooding incidents in the city. The flooding was attributed by residents to the city's layering of new asphalt onto an adjacent street, and to the city's sanitary sewer disconnection program.

1320 S. University Rezoning

The council was asked to consider a request to conditionally rezone 1320 S. University – from D2 (downtown interface) to D1 (downtown core).

The request included setting conditions on the D1 designation, such as restrictions on height and floor area that are less than what's allowed in "unconditioned" D1. For example, the by-right height limit in D1 is 180 feet, but one condition the owner of the property – Philip Sotiroff – wanted to place on the property was a 145-foot height limit.



The magenta parcel and arrow indicate the 1320 S. University parcel proposed for conditional rezoning to a higher density use that's found in the dark brown (D1) areas to the west and north. The light brown area to the south and west is D2 (downtown interface). Light green is PL (public land). Yellow is R2B and dark purple is R4C – both residential zoning. (Image links to higher resolution image.)

That 145-foot limit, however, is more than twice the limit of the parcel's current D2 zoning, which allows buildings only as tall as 60 feet. Currently at the site – on the south side of South University, between Forest and Washtenaw avenues – is the three-story Park Plaza apartment building.

The site is adjacent to a D1 parcel to the east, where the Landmark apartment building is being constructed, at 601 S. Forest. But the 1320 S. University property also abuts lower-density residential zoning. Single-family homes are located to the south of the site, and a fraternity is located to the west.

The South University area was an intensely debated part of the A2D2 downtown rezoning initiative, which the city council finally ratified on Nov. 16, 2009 after more than two years of planning work. As part of that process, the city planning commission had initially recommended a zoning map that assigned D1 zoning to the 1320 S. University parcel. The city council subsequently drew the lines differently, which resulted in a D2 designation for the parcel, and sent the map back to the planning commission. The planning commission then revised some parts of its map, including the designation for 1320 S. University.

More recently, at its Feb. 7, 2012 meeting, planning commissioners voted unanimously not to recommend that 1320 S. University be rezoned from D2 to D1.

Council on S. University Rezoning: Public Hearing

Marc Gerstein introduced himself as a resident of Forest Court, and since 1982 the owner of a house that abuts the south boundary of a parking lot at the rear of 1320 S. University. He noted that any change in the zoning will affect him directly. He urged the council to follow the staff report and the unanimous recommendation of the city planning commission and to reject the request for conditional rezoning from D2 to D1.

He noted that the planning staff report finds that D2 was warranted for the parcel and was carefully considered by the city planning commission and the council. The staff had found there was no error in that decision. He noted there'd been no changes in the neighborhood since passage of A2D2 two years ago. To rezone the parcel now would strip away any buffer between the small residential houses and the 1320 S. University parcel. He concluded by asking the council to deny the petition for rezoning.

Council on S. University Rezoning: Council Deliberations

Tony Derezinski (Ward 2), who is the city council's representative to the city planning commission, described the location of the parcel proposed to be rezoned. Two high-rise buildings stand to the west at South University and South Forest – University Towers on the northwest corner and the currently under-construction Landmark Building (formerly called the 601 S. Forest). To the east stands a fraternity house. Derezinski noted the A2D2 zoning ordinances had been adopted after considerable debate. The planning commission had unanimously agreed with the recommendation of the staff that the parcel not be rezoned, he said.

Christopher Taylor (Ward 3) also concurred that the prior community conversation had been rigorous and extensive and warrants the council's respect.

Jane Lumm (Ward 2) added that she felt having a buffer in the form of D2 zoning makes a great deal of sense.

Outcome: The council unanimously rejected the proposed conditional rezoning of 1320 S. University.

The city council's vote was just its initial consideration of the request – a "first reading." A rezoning request, like any ordinance change, requires initial approval, followed by a public hearing and a final vote at a subsequent meeting. Often, councilmembers will advance an ordinance change to a second reading, if they have not settled on a position and are interested in hearing the sentiments that might be expressed at a public hearing. So the fact that the council rejected the proposal on first reading can be taken as a measure of the council's especially strong opposition to changing the zoning that was agreed on as part of the A2D2 process.

Tim Hortons Site Plan

On the April 16 agenda was a site plan for a new Tim Hortons restaurant at 3965 S. State St. The site plan had received a unanimous recommendation for approval by the Ann Arbor planning commission at its March 6, 2012 meeting. The site is located on the east side of the street, near the intersection of State and Ellsworth.

The plan calls for demolishing a vacant building on the 2.23-acre site where previous restaurants, including Enzo's and Gallagher's, were located. In its place, a one-story 1,953-square-foot restaurant with drive-thru facilities would be built on a 1.18-acre site divided from the current parcel. The building would face West Ellsworth and use an existing shared drive on South State, as well as a relocated drive onto West Ellsworth. An outdoor seating area is proposed on the east side of the building.

The property is zoned C3 (fringe commercial), which allows for construction of a drive-thru restaurant. The planning commission's recommendation of approval was contingent on two issues: (1) submission of a tree health evaluation form, and (2) approval of the parcel's land division, prior to the city issuing permits for construction of the new building.

Much of the discussion among planning commissioners at their meeting had focused on the proposed roundabout at State and Ellsworth. A spokesman for Tim Hortons said they'd found out about the roundabout plans late in the process, but were working to integrate their own plans to accommodate it. He indicated that if the company gets approval from the city, they hope to open in August. Construction for the roundabout is expected to begin in the spring of 2013, with completion in the fall of that year.

During council deliberations on April 16, Tony Derezinski (Ward 2), the city council's representative to the planning commission, made some brief remarks. He described it as a property that's been vacant for a couple of years. It would be a great improvement, he said. The planning commission went through ingress and egress issues. Derezinski said he felt it adds value and would be a good place to get coffee in the morning.

Sabra Briere (Ward 1) noted that the State Street corridor is currently undergoing a study. She wondered how this particular project fits into the ongoing discussions that the corridor study group has had. City planning manager Wendy Rampson told Briere that it doesn't really fit into ongoing discussions on the corridor, but it does remove a relatively blighted building on the site. The corridor study has not gotten as far as making land use recommendations yet, Rampson said.

Responding to a question from mayor John Hieftje, Rampson said that the plan is to begin construction in May. Tim Hortons is moving in a timely way, she said. A land division needs to be completed before they can start, she said. And the Tim Hortons team is coordinating with the Washtenaw County team that is planning the roundabout at Ellsworth and State. She figured in a couple of months, construction might start.

Outcome: The council voted unanimously to approve the Tim Hortons site plan.

AAA Request for Parking Zoning

Before the council for its consideration was initial approval to a proposal from AAA Michigan to rezone half of a parcel located at 1200 S. Main to P (parking). To take effect, the initial approval from the city council would need to be followed by a second and final approval following a public hearing at a subsequent meeting.

The rezoning to P (parking) is part of a two-parcel site plan proposal – for which the city planning commission provided a positive recommendation at its March 6, 2012 meeting. At that meeting, the commission took two votes on the 1200 S. Main parcel – the site plan and the rezoning proposal. And on both votes, the planning commission split 6-3. For the other, adjacent parcel at 1100 S. Main, the city planning commission voted unanimously to recommend the site plan for approval.

In front of the city council on April 16, however, was just the resolution to rezone a portion of the 1200 S. Main parcel to P (parking).

The two parcels, at 1100 and 1200 S. Main, are across from Michigan Stadium. An AAA branch built in the 1950s is located there. The owner wants to build a new branch on a different part of the site, tear down the existing building, and reconfigure parking spaces.

The two parcels are part of a 1.5-acre site containing four parcels owned by the auto club and all zoned O (office). Located on the 1200 S. Main parcel is the current one-story branch building with walk-out basement and 36 parking spaces, with exits onto South Main, Berkley and Potter.

The 1100 S. Main site is a surface parking lot, which has 72 spaces and exits onto both Potter and Keech. The owner is requesting to build a one-story, 5,443-square-foot new branch building on the northeast corner of that site, with parking for 21 spaces. A second phase of the project would include an eventual 2,230-square-foot addition to the south side of that building. There are six landmark trees on the site, and the plan would require removal of two that are located along South Main, near Keech. Other trees would be added elsewhere on the site.

After the new structure is completed, the old building at 1200 S. Main would be torn down and a 14-space parking lot would be put on that parcel. And to do that, the proposal asks that the northern 123 feet of that parcel – about half of the parcel – be rezoned from O (office) to P (parking), so that parking could become the principal use for that site. A site plan for that parcel is also required. The rezoning to P (parking) is what the city council considered on April 16.

The owner's overall plan called for a total of 35 spaces – a reduction from the current parking on the site, which was approved in the mid-1970s but no longer conforms with existing zoning. The 35 spaces would be four more spaces than the 31 maximum number permitted under the O (office) zoning, based on the new building's square footage in both phases. That's why the owner requested that a portion of the overall site be rezoned for parking – in the P (parking) district, there is no maximum.

AAA Request for Parking Zoning: Council Deliberations

City planning manager Wendy Rampson was asked to the podium to summarize the proposal, which she did. The current configuration has the AAA office sitting on the parcel to the south, with surface parking on the parcel to the north. She said the configuration was approved in the 1970s based on an interpretation that parking would be allowed on the northern parcel, based on the ownership by AAA of both parcels. The city does things differently now – if there's no other use on a parcel besides parking, then the city requires that it be zoned P (parking).

Rampson described what AAA wants to do as a "flip flop" – build a new branch office on the northern parcel and put parking on the south parcel. It's that south parcel that AAA wants rezoned. She noted that the city planning commission vote was 6-3 on rezoning. Staff also had some concerns about approving parking as a principle use, because that's something the city is trying to get away from. The plan has a lot of benefits with respect to stormwater detention, she said, and reduces the amount of impervious surface across the two sites, as well as the total amount of parking.

Tony Derezinski (Ward 2) said the site plan really did sell the proposal. The building that AAA is putting up is an improvement over the one that's currently there. The old building has a lot of mileage on it, he said. With its location across from the University of Michigan football stadium, the building would be noticed by a large number of visitors to Ann Arbor, he said.

Rampson added that it's a two-phase project. In the new building, AAA anticipates adding more services, so that's the rationale for wanting to have parking available on both parcels.

Carsten Hohnke (Ward 5) said he felt like the project is a step in a better direction, but not what the city would want if the project were starting from scratch. He wondered what AAA's plans would be if the council turned down the request to rezone. Rampson said she didn't know. Before AAA brought forward their proposal, however, they'd gone over ways to solve the parking issue without rezoning. One possibility would be to retrofit the existing building. They also considered different configurations that would reduce the amount of parking. But ultimately AAA did not want to pursue those, she said.

Mike Anglin (Ward 5) asked if there'd been given any consideration to moving the building further away from the sidewalk, and he wondered if AAA could be forced to comply with a greater setback requirement. Rampson reminded Anglin that the recent area, height and placement revisions had reduced the amount of setback required – which in this case allowed the building to be moved further way from the residential area to the west and closer to Main Street. Rampson also explained that the curbcuts to Main Street would be removed.

Stephen Kunselman (Ward 3) wanted to know what assurance the council would have that the old building will be torn down. Rampson explained that once it's zoned P (parking), the building couldn't be used for anything. And AAA is not intending to keep the building in place – the space is needed for parking.

Outcome: The council gave unanimous initial approval to the AAA Michigan rezoning request for 1200 S. Main.

Annexation Rezonings

The council was asked to consider initial approvals of six separate rezoning requests associated with annexation into the city of Ann Arbor from Scio Township. The zoning change in all cases is from the township to a residential category.

Five of the properties were annexed into the city on Oct. 3, 2011 – in connection with the expansion of a well-prohibition zone due to 1,4 dioxane groundwater contamination caused by the Pall Corp.'s Wagner Road facility, formerly owned by Gelman Sciences. Those five properties are: 305 Pinewood St.; 3225 Dexter Rd.; 427 Barber Ave.; 545 Allison Dr.; and 3249 Dexter Rd.

Annexation into the city allows the properties to connect to city of Ann Arbor water services. Pall has paid all petition filing fees as well as the connection and improvement charges for water and sanitary sewer service that are related to the annexations. The zoning for which the city council gave initial approval is for R1C (residential). [Google map of well prohibition zones and property locations] [.jpg of map with well prohibition zones and property locations]

A sixth parcel for which the council gave initial rezoning approval – also due to annexation, but not related to the well-prohibition zone – is located at 1575 Alexandra Blvd. The parcel was given initial approval to be rezoned from the township to R1A (residential) zoning.

As ordinance changes, all rezoning requests require an initial approval from the city council, followed by a public hearing and a final approval at a subsequent meeting.

Sabra Briere (Ward 1) offered the only council comment on any of the annexation-related rezoning requests, noting that they all went from township zoning to single-family residential.

Outcome: The council unanimously approved all the annexation-related rezoning requests. The requests need to come back for a second and final approval by the council, after a public hearing.

Ann Arbor Airport Study

On April 16 the council considered four different resolutions in connection with Ann Arbor's municipal airport, three of them connected to the completion of an environmental assessment of a proposed 800-foot lengthening of the airport runway.

The city council had initially authorized funding for the assessment project at its Feb. 2, 2009 meeting. The assessment began on May 4, 2009. The process appeared to culminate in a public hearing in April 2010. [See Chronicle coverage: "Ann Arbor Airport Study Gets Public Hearing."] In the interim, city councilmembers have removed the runway extension from the city's capital improvements plan (CIP) each year they've been asked to give the CIP its annual approval.

However, when the Federal Aviation Administration responded to the draft report, that prompted communication between the city of Ann Arbor and the FAA. And that back-and-forth has resulted in FAA requests for more work, which is meant to wrap up the environmental assessment (EA). From the staff memo accompanying one of the resolutions:

The FAA's response was received nearly a year later (September, 2011). The remaining work on the EA includes modifications based on the FAA comments, coding public and agency comments and responses for the final EA document, preparation of the Errata and FONSI for submission to MDOT-Aero. There is about 2-3 months of work remaining to complete the EA.

One of the resolutions authorizes $800 for an additional map to be prepared by URS Corp., one of two consultants that the Michigan Dept. of Transportation is using for the project. The amount is covered by MDOT's project contingency budget. This item is not specifically related to the environmental assessment.

A separate resolution authorized $12,000 of additional consulting work, also with URS. A third resolution authorized an additional $26,552 worth of consulting work from SmithGroupJJR. The additional work by URS and SmithGroupJJR is being covered by a $45,000 grant program, which consists of $42,750 in federal funds, $1,125 in state funds and $1,125 in airport matching funds (the city's portion.) Authorization of the grant program was the fourth airport-related item on the agenda.

Ann Arbor Airport Study: Public Comment

During public comment, **James Vincze** introduced himself as a member and vice chair of the airport advisory committee. He urged the council to complete the airport runway extension study. It's important to get the process completed, he said. Significant time and resources have already been spent and the public has been involved. Matt Kulhanek is a good airport manager, he said. Voting to complete the study doesn't mean the council favors runway extension, he said. Rather, it means the council wants to get the facts out and have a complete study and analysis.

Ann Arbor Airport Study: Council Deliberations

Airport manager Matt Kulhanek was asked to the podium to answer questions. Jane Lumm (Ward 2) began by asking why the city is continuing to spend money to study the runway extension, when the council had consciously removed the extension from the city's capital improvements plan. She had a hard time reconciling that, even though the amounts of money weren't actually all that large.

Kulhanek pointed out that the first airport-related item on the agenda – the $800 for the map preparation – was not related to the environmental assessment.

So mayor John Hieftje then asked the council to vote on that item. And that vote was unanimous in favor.

Kulhanek noted that the council's direction had been to get the facts on the proposed runway extension and that direction had come on two occasions, with votes to fund the environmental assessment. He said the council's subsequent action to remove the runway extension from the capital improvements plan was based on a concern that by including it in the capital projects budget, it reflected a de facto support of actually doing the project. But at no time has the staff received direction to pull back from completing the environmental assessment. Kulhanek indicated that another grant agreement would be coming to the council later, after the one they were considering that evening.

Jane Lumm (Ward 2) talks to Kathe Wunderlich (back to camera)

Mike Anglin (Ward 5) asked for clarification of the unexpected review by the FAA technical committee to which the staff memo had referred. Kulhanek explained that when the document was first entered into the system, the city was not expecting further FAA review. But two weeks ago, he said, the city received notification from FFA technical operations, a branch within the FAA, indicating that branch would need to sign off on it. The reason that technical operations would need to review it was due to two sets of navigational aids that would be relocated if the runway project moves forward. The document had already been given an 11-month review by the district office of the before the council meeting. Wunderlich has worked as part of a citizens group opposing the runway extension.

FAA, and the conclusion had initially been that the technical operations division didn't need to review it. At that point, the city had the understanding the FAA was finished. That changed in the last two weeks, when city staff found out that FAA technical operations would need to review it.

Stephen Kunselman (Ward 3) asked if the resolution that night was specifically for the relocation of navigational aids. No, replied Kulhanek. A resolution to approve another grant for that would come some time in the future. The grant before the council that night was to finish up the documentation of the environmental assessment and get it in a final format to submit to the FAA for review. What would come back to the council later is a reimbursement agreement for the work the FAA will have done to review the documentation.

Sabra Briere (Ward 1) briefed Stephen Kunselman (Ward 3) before the start of the meeting. They both voted against the grant funding for the environmental assessment of the airport runway extension.

Kunselman said he was confused why there'd be the need for another reimbursement agreement. Kulhanek reviewed the purpose of that night's grant agreement.

Sabra Briere (Ward 1) was up next to question Kulhanek and she apologized for putting him on the spot. His reply indicated he'd anticipated lots of questions: "That's okay, I didn't think I was going to get a pass tonight!"

In 2009, Briere said, the council had approved two grants and in 2010 the council had approved an additional grant. At the time, she said, she thought that the EA document was in draft form and almost complete. Kulhanek indicated that was not the case. The grant funding in 2009 had kicked off the project, he said. When the 2009 grants were approved, the city had also approved contracts with the two engineering firms.

Briere summarized what the council was considering as funding additional work by the engineering firms to get the EA document into shape to be submitted to the FAA. Kulhanek indicated that was basically right. The work the two firms would do would in essence finalize the document for everything except the FAA technical operations review. That review will have a specific scope – just the impact on the navigational aids.

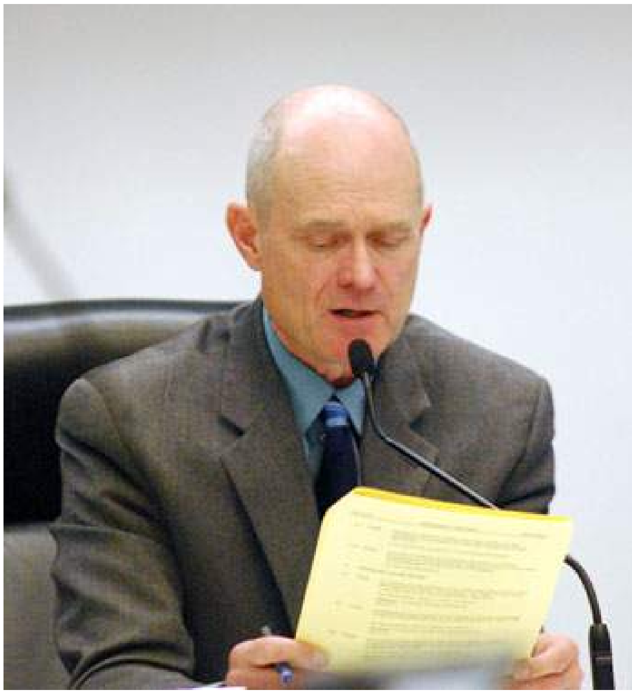
Responding to a question from Briere, Kulhanek explained that the EA would cover more than just a discussion of navigational aids. It would include economic impacts, physical impacts, noise impacts, and wetlands impacts. There's a whole variety of things that are included. It's a broad document that includes public comment, as well as input from various agencies like the county road commission, county water resources commissioner and the like.

Briere said she had trouble understanding why an environmental assessment would take four years.

Hieftje asked if Kulhanek saw a benefit to the city and users of the airport, if the council does not want to go ahead with the runway extension, once the process is completed. Kulhanek told the mayor that he felt the biggest benefit would be to finishing what they've started back in 2009. The council would be able to make a decision based on an actual study of what the impacts are – not what our gut feels or our heart feels. A decision could be based on actual data and feedback from the public and various agencies and everyone involved. Kulhanek said there's already been a lot of time and money invested in getting to this point in the project, and he thought it's important to follow through to have solid information. If the council chooses not to go forward on the runway project, it can make that choice.

Hieftje started adding up the money in the request. He asked Kulhanek how much more money would need to be spent – local as well as other money – to complete the project. Kulhanek said the first three grant agreements totaled $309,000.

The city's share of that had been $7,725. From a local perspective, he said, that's a minor cost. The



Mayor John Hieftje opposed the grant funding for completion of the environmental assessment for an extension of the Ann Arbor municipal airport.

grant agreement before the council that night was for $45,000 with a local share of $1,125. The next and last grant agreement will be around $30,000. The total for the EA would be around $385,000 with a local share of less than $10,000, Kulhanek said.

Kulhanek estimated that it would take the consultants another two months to do the additional work. He thought that three to six months from now, the last grant agreement would be back in front of the council for approval. Assuming three to four months for review, Kulhanek estimate that it would be early 2013 before the process was complete.

Hieftje asked again if there was some benefit to the environmental study, beyond knowing the impact of the runway extension. Kulhanek said it's good information. Knowing the noise levels is useful. Knowing about bird species is also useful, he said. There are some mowing restrictions to protect their habitats.

Kunselman contended that everything Kulhanek had just mentioned as beneficial had already been done, so what the council was being asked to do was approve more money for consultants to wrap things up. He said the city continues to throw money at a project at the end. He said he'd vote no on everything. It's taxpayer dollars, whether it's local or federal. He said his constituents don't want the runway extension and he'd vote no on that, too. The consultants can wrap it up without additional money, he said. He said he was done throwing money at this kind of thing.

Lumm said she'd been struggling with this. She allowed that it was a very small city share. Ultimately though, what the council would be doing is spending money on something that won't move forward. She reiterated the fact that the council had removed the project from the CIP, which she translated into a decision that the council wouldn't move forward. Kulhanek ventured that the council might be "wowed" by the EA and perhaps be open to the possibility of extending the runway.

Outcome: The main resolution, on the $45,000 grant, was approved on a 7-4 vote. Voting for a grant contract with the Michigan Dept. of Transportation were Sandi Smith (Ward 1), Tony Derezinski (Ward 2), Christopher Taylor (Ward 3), Margie Teall (Ward 4), Marcia Higgins (Ward 4), Carsten Hohnke (Ward 5) and Mike Anglin (Ward 5). Opposing it were Sabra Briere (Ward 1), Jane Lumm (Ward 2), Stephen Kunselman (Ward 3) and mayor John Hieftje. Both contracts with the consultants were opposed by Lumm and Kunselman. Hieftje joined them in opposing the contract with SmithGroupJJR.

Street Repair

The council was asked to consider two major contracts involving street resurfacing and reconstruction. One was a second large contract for street resurfacing work this season – $4,054,599 with Barrett Paving Materials Inc. At its previous meeting on April 2, 2012, the council had authorized a $3.6 million contract with Barrett for an initial set of streets to be resurfaced. The project includes a $405,000 contingency.

The second set of streets includes portions of the following: South Seventh Street, Mt. Pleasant Avenue, Park Drive, Mt. Vernon Avenue, Manhattan Drive, Meadowbrook Avenue, Martha Avenue, Palomar Drive, Catalina Avenue, Eton Court, South Forest Avenue, Vinewood Blvd., Dorset Road, Berkshire Road, Woodside Road, Londonderry Road, Tremmel Avenue, Page Court, Pine Valley Court, Esch Avenue, and Esch Court.

Also at the April 16 meeting, in connection with the regular street resurfacing program, the council considered a $143,455 contract with a different company, CTI and Associates Inc. (CTI), for construction materials testing services. The materials to be tested include oils, aggregates, asphalt, and concrete. Funds for the street resurfacing projects are drawn from the city's street repair tax, which voters agreed to renew in November 2011 for another five years, through 2016.

Another road construction project on the agenda was a contract with Dan's Excavating Inc. for $2,314,951 for replacement of two old water mains and resurfacing of the East Stadium Boulevard from Washtenaw Avenue to Packard Street. The total project is estimated to cost $3,600,000. Of that amount, $1,400,000 will come from the water fund capital budget and $2,200,000 will come from millage approved capital budget.

The East Stadium project will maintain the existing five lanes of vehicular traffic, and new bike lanes will be added on both sides of the street.

Also on the agenda was a materials testing contract for the East Stadium Boulevard project – $50,185 with Inspection Services Company Inc.

The only substantive discussion on the four items was on the materials testing. Mike Anglin (Ward 5) asked why the materials testing was being done. City project engineer Igor Kotlyar explained that such testing is always done for such projects. It's a standard testing procedure, he said. Some of it involves making sure the proper materials are delivered to the site. But it also involves making sure that the materials are properly deployed as the project work is done.

For example, when a water main is backfilled with sand, it's tested to make sure that the sand is compacted to the proper density. Gravel that's put into the road bed is also tested for property compaction, Kotlyar explained. Homayoon Pirooz, head of project management for the city, responded to a question from Anglin by explaining that the city itself is not certified to perform that kind of testing, and does not have the certified equipment to do that. He indicated that it's essentially a specialty.

Outcome: The council unanimously approved the four resolutions involved with street resurfacing and reconstruction work.

Fire, Police Retirement/Health Changes

On the April 16 agenda was a resolution for final approval of changes to the employee retirement system to accommodate recent changes to the collective bargaining agreement with the city's police command officers union and firefighters union. Also before the council was final approval to revisions of the retirement health care benefits to reflect changes to those collectively bargained agreements.

Changes to the retirement system include: (1) increasing the pension contribution of command officer members to 6% from 5%; (2) implementing a pick-up feature as permitted by the Internal Revenue Code for the pension contributions of firefighters and command officers, converting their 6% pre-tax contribution to a 6% post-tax contribution; (3) increasing the vesting and final average compensation requirements for firefighters hired after July 1, 2012; and (4) implementing a federal provision that allows eligible retired public safety officers to pay qualified health insurance premiums directly from their pensions.

The change to the retiree health care system stipulates that new hires after July 1, 2012 will be eligible for an access-only health care plan at the time of their retirement, instead of a city-paid retiree health care plan.

Fire, Police Retirement/Health Changes: Public Hearings

On the retirement changes for police command officers and fire personnel, **Thomas Partridge** questioned whether the public had been fully informed on the substance of the change. He felt that representatives of the police department and the union representatives involved in the contract negotiations should have been present to explain their side of the issue.

Edward Vielmetti flipped through the pages of the ordinance revision in the three-ring binder that holds the council agenda, and counted out the number of pages that had been red-lined as he flipped through them. When he got to 16, he did not continue counting, but noted that more than 16 pages of the ordinance have been amended. He stated that he had no idea how councilmembers could evaluate whether this is a good idea or a bad idea. He said that he himself (if he were a member of council) wouldn't know what to do with a proposal like that. He hoped the city was making a wise choice.

On the retiree health care benefits, Partridge complained that Gov. Rick Snyder and former city administrator Roger Fraser [who now works for the state as an assistant state treasurer] are attempting to erode benefits to public employees, including those in high-risk jobs.

Fire, Police Retirement/Health Changes: Council Deliberations

On the retirement changes, Sabra Briere (Ward 1) said she believed the primary changes reflect the bargained-for benefits from recent union settlements. The city is taking advantage of IRS rules, she said.

On the retiree health care changes, Jane Lumm (Ward 2) said that the changes to the ordinance were consistent with the changes to the access-only health plan that had been adopted by the command officers and firefighters.

Outcome: The council unanimously approved the ordinance changes affecting retirement and health care benefits for police command officers and firefighters.

0.17 BAC as Separate Offense

The council considered final approval to a change in the city's traffic ordinance to adopt a provision of the Michigan Vehicle Code – which establishes driving with a blood alcohol content (BAC) of more than 0.17 as a separate offense from operating under the influence. The council had given its initial approval to the ordinance change on April 2.

The Michigan legislature had previously changed the MVC, which Ann Arbor has adopted, to include the separate charge for the very high BAC of 0.17. However, the legislature did not at that time change the Home Rule Cities Act to allow cities to impose the greater penalty of 180 days in jail and/or $700 fine that comes with the BAC 0.17 charge. But in February 2012, the legislature amended the Home Rule Cities Act to allow for that penalty. Ann Arbor is making the change to its local ordinance in order to be able to charge drivers with the 0.17 offense.

Records from January 2010 through February 2012 provided to The Chronicle by CLEMIS (Courts and Law Enforcement Management Information System) show three instances of 0.17 offenses – which could not at the time be charged as a separate offense. The CLEMIS records for the same time period also show three reports for the moderately higher BAC level of .08, which could already be charged separately from operating under the influence. [.jpg of bar graph of OWI offenses]

As a change to the city's ordinances, the change required a second vote and a public hearing (which is separate from the general public commentary held at the start of the meeting.)

0.17 BAC: Public Hearing

Edward Vielmetti led off the hearing by asking where a copy of the proposed changes to the ordinance might be found. Mayor John Hieftje told him it was available online or in a large three-ring binder near the podium – which **Thomas Partridge** had been perusing. Vielmetti then reviewed the ordinance change, while Partridge held forth.

Partridge began by complaining about Hieftje's standard boilerplate recitation of the rules for public hearings, which include a provision that speakers confine their remarks to the topic of the public hearing. Partridge construes the rule as a way of inappropriately limiting free speech.

On the substance of the ordinance change, Partridge said it would have been better to attach a resolution that would stop people who are high on alcohol and drugs from driving or causing disruptive behavior in the city of Ann Arbor. He called for a parallel amendment to go forward, that would encourage and require all retailers and bars serving alcohol and supermarkets selling alcohol, to note the names and identity of people who purchase alcohol. He also called for bars to refuse service to patrons who have visited other bars before arriving, who are clearly under the influence of alcohol, and who intend to drive.

Based on his review – while Partridge was speaking – of the ordinance changes, Vielmetti said it appeared to him that the ordinance changes would increase the penalties for driving "super drunk." He pointed out that there are a number of students in Ann Arbor who don't just drive relatively drunk, but who also walk relatively drunk. And they may be so drunk that they pose a danger to others while driving, but also to themselves due to alcohol poisoning.

From reading the student press, Vielmetti said it's his understanding that there's a concern about prosecution for those who help their classmates who are trying to obtain treatment for alcohol poisoning – because they might be slapped with a "minor in possession" citation themselves. He cautioned the council not to overly hastily increase the penalties for drunken behavior, without also addressing the needs of those who need to receive treatment. It would be unfortunate to put yourself in a situation where you thought you were making an improvement, and then create some unintended consequences, he said – people driving themselves home, because they weren't ready to help their friends walk themselves home.

0.17 BAC: Council Deliberations

Sabra Briere (Ward 1) alluded to Vielmetti's comments during the public hearing, by saying she liked the idea of finding a solution for adolescents who are at risk of underage drinking violations. She felt the decision was straightforward. People who have 0.17 BAC should pay a heavier penalty, she said.

Stephen Kunselman (Ward 3) asked if the state law on 0.17 BAC was already in effect for people on University of Michigan property. Assistant city attorney Abigail Elias responded to the question by saying that for the "super drunk" provisions, which are for driving or operating a vehicle, the change to the ordinance simply brings it into conformity with the state law. If anyone were driving where the city did not have jurisdiction, she said, state law would apply.

Kunselman followed up by asking if UM's department of public safety already has the authority to enforce the 0.17 BAC provisions on the Ann Arbor city streets. Elias told Kunselman that Ann Arbor police officers would enforce the law on city streets. She said she did not know if UM DPS officers were enforcing state law on city streets. That's a question she could not answer, she said. Mayor John Hieftje said his understanding was that UM DPS officers have the ability to enforce laws on Ann Arbor city streets, but it's unusual for them to do so. He stated that he'd be happy to see UM DPS join in helping out on the "party patrol" that the Ann Arbor police department uses to police student neighborhoods on evenings when parties are frequently held.

Outcome: The council unanimously approved the 0.17 BAC ordinance change.

Selection of Auditor

The council was asked to consider a five-year contract for independent auditing work with The Rehmann Group – based on its $344,500 bid. The contract allows for two one-year extensions.

Margie Teall (Ward 4) chairs the council's audit committee.

Abraham & Gaffney, the firm that the city has used for the last few years, also bid on the work. The Abraham & Gaffney bid came in at $387,500. Two other firms also bid for the city of Ann Arbor auditing work: Andrews, Hooper, Pavlik PLLC ($340,500); and Doeren Mayhew ($361,300).

Andrews, Hooper, Pavlik's was the low bid, but the selection was not made purely on price. The amount of the bid counted for 30 points out of a possible 100. The other two categories were "expertise and experience" (40 points) and "auditing approach" (30 points). Rehmann and Abraham & Gaffney both scored the maximum 70 on the categories other than price. The memo accompanying the resolution indicates that the choice was also based on "a desire to periodically change service providers." [.pdf of scoring metric and comments]

For Rehmann, then, the fact that it was *not* the incumbent firm was an advantage for the city auditing contract award. Last year, when it competed for the Ann Arbor Transportation Authority's auditing contract, Rehmann had found its incumbent status to be a *disadvantage*. Because of the auditor rotation policy the AATA board had adopted on June 16, 2011, Rehmann was not eligible for selection when the AATA board opted to award the contract to Plante & Moran on Sept. 15, 2011.

Selection of Auditor: Council Deliberations

Margie Teall (Ward 4) introduced the resolution as chair of the audit committee, indicating that she was pleased that the audit committee had been asked to be a part of the selection and evaluation process. The audit committee had been pleased with the representative from Rehmann who had interviewed with the committee.

Jane Lumm (Ward 2) said she supported the selection of Rehmann, saying that it was considered best practice to rotate auditors and that Rehmann is well respected. She asked about the notation in the evaluation of proposals that indicated Rehmann projected using 200 hours less than Abraham & Gaffney. She asked if the city is comfortable with that.

Sandi Smith (Ward 1), who also serves on the audit committee, noted that the auditor's contract is a multi-year contract. The firm will need fewer hours as they get more familiar with the city's auditing project over time.

Outcome: The council unanimously approved the selection of The Rehmann Group as the city's auditor.

Hearing on Sakti3 Tax Abatement

On the agenda was a resolution to set a public hearing for May 7 regarding a tax abatement for

Sakti3 – an Ann Arbor-based battery technology spinoff from the University of Michigan. Sakti3 is led by UM professor Ann Marie Sastry.

According to the staff memo accompanying the resolution, Sakti3 is requesting an abatement on $151,433 of real property improvements and $1,374,861 of new personal property. If approved, it would reduce Sakti3 Inc.'s annual tax bill by $23,200 for each of three years in the recommended abatement period. The new building improvements and personal property investments would generate about $29,500 in property taxes for each year during the abatement period.

Previously, the council voted on March 21, 2011 to set a public hearing on the establishment of the industrial development district under which Sakti3 is applying for an abatement. And on April 4, 2011, the city council voted to establish the district.

Outcome: Without comment, the council unanimously approved setting a May 7 public hearing on a tax abatement for Sakti3.

Digital Billboards

The council was asked to consider a 180-day moratorium on two items: (1) city staff consideration of applications to erect digital billboards; and (2) the erection of digital billboards.

Coming under the temporary moratoria are "billboards commonly referred to as 'electronic message centers,' 'electronic message boards,' 'changeable electronic variable message signs,' or any billboard containing LEDs, LCDs, plasma displays, or any similar technology to project an illuminated image that can be caused to move or change, or to appear to move or change, by a method other than physically removing and replacing the sign or its components, including by digital or electronic input."

The resolution acknowledged that such signs are already prohibited by the city's sign ordinance. From that ordinance, the list of prohibited signs include those that "…incorporate in any manner or are illuminated by any flashing or moving lights other than for conveyance of noncommercial information which requires periodic change."

The resolution was added late to the agenda, after printed copies of the agenda were made for the council chamber audience. Based on the time stamp on the online agenda, the item appears to have been added at 6:48 p.m. – for the council meeting scheduled to start at 7 p.m. The item was sponsored by mayor John Hieftje.

Sabra Briere (Ward 1) said she was confident there are some places for digital billboards in our lives, but she did not want to see them on crowded downtown Ann Arbor streets. Imposing a temporary moratorium on whether to allow them in the city limits made sense to her, she said.

Mike Anglin (Ward 5) said that many of the billboards in the city had 30-35 year leases on them, and it becomes complex to get them removed. He said that Adams Outdoor Advertising had been asking to "do trades" for many years. As issues for the public, Anglin identified distractibility while driving and "virtual vision pollution." He gave the corner of Madison and Main, late at night, as an example. It looks like you're coming into an entertainment area, he said, like vaudeville or something. He called for a community discussion about whether to have digital billboards. Do they bring value? he asked. He didn't want to make the decision piecemeal.

Outcome: The council unanimously approved the temporary 180-day moratorium on digital billboards.

Personal Computer Replacement

The council had on its agenda a $450,000 purchase order with Sehi Computer Products to cover the replacement of personal computers over the next two years.

The project budget includes the purchase of a minimum of 305 desktops and 195 laptops. Funding for replacement of the city's computers comes from the information technology services unit.

Sabra Briere (Ward 1) asked for an explanation of the city's replacement policy. Paul Fulton, the city's IT service delivery manager, described how the replacement cycle for desktop machines and special-purpose laptops is five years. The replacement cycle for general purpose laptops is three years. About four years ago, he said, the city did a general refresh, and those machines are now coming due for replacement – a total of about 500 machines.

Outcome: The $450,000 purchase order with Sehi Computer Products was unanimously approved.

Biosolids Contract

The council considered a contract with BioTech Agronomics Inc. to spread biosolids from the wastewater treatment plant on agricultural fields – during April to December. The rest of the year, the material gets landfilled. The contract pays about $0.0321 per gallon, which works out to approximately $514,000 per year.

Paul Fulton (right, foreground) is typically on hand before the council meetings start, to handle any computer issues councilmembers might have. On April 16, he was called to the podium during the meeting to explain the computer replacement cycle.

Stephen Kunselman (Ward 3) wanted to know where the material was going. Ed Sajewski, contract/project services manager for the wastewater treatment plant, explained that it would be spread on farm fields in the outlying area. He described the nutritive benefit – carbon, nitrogen, phosphorus – of applying the material to fields, as opposed to just landfilling it. Kunselman wondered if there were testing procedures to make sure no heavy metals were in the material. Yes, replied Sajewski, the city has a lab to do that testing, and it's required to be done through the permit the city has with the U.S. Environmental Protection Agency.

Outcome: The council unanimously approved the $514,000 contract for spreading of biosolids.

Mowing Contracts

The city council considered three contracts for mowing different city-owned properties – traffic islands, areas of the wastewater treatment plant, and neighborhood athletic fields: (1) Green-Vision Lawn & Landscaping ($105,336 for 3 years); (2) A2 Outdoors Creations ($43,275 for 3 years); and (3) KBK Landscaping for mowing and trimming services at neighborhood athletic fields and five city locations in the amount of $17,190/year ($51,570 for 3 years).

Sabra Briere (Ward 1) said that people who drive into the city would have a right to complain if the city didn't maintain the traffic islands. Logistically, she described it as a challenge to get the mower out to the locations and to then mow just five square yards.

Stephen Kunselman (Ward 3) asked about the four parks that are a part of the contract – which parks? Matt Warba, acting field operations manager, told Kunselman the four are: Miller Nature Area, Forsythe, Kempf House and 875 S. Maple. Warba confirmed what Briere had said about the logistical challenge of mowing the areas covered in the contracts. He said there are 184 traffic islands. The city's strength is mowing large areas of grass, not the small intricate areas like traffic islands or the areas around Kempf House, a museum located on South Division.

Outcome: The council voted unanimously to approve the mowing contracts.

City Hall Restrooms

Pulled out of the consent agenda by Jane Lumm (Ward 2) for separate consideration was a $93,438 contract with LC Construction LLC. The project involves the construction of five unisex restrooms, on floors 2-6, in the old elevator tower of city hall.

Lumm was dissatisfied with the answer she'd received from staff before the meeting to a question about why the bathrooms had not been constructed as part of the overall municipal center renovation project.

She characterized the response she'd received as essentially, "We ran out of money." She wanted all the costs for such projects captured in one place.

Otherwise, it's hard to understand which costs are related to city hall renovation and which are not, she said.

Outcome: The council unanimously approved the restroom construction contract.

Before the council meeting, Jane Lumm (Ward 2) talked with city administrator Steve Powers (left).

Placid Way Park Improvements

Pulled out of the consent agenda by Sabra Briere (Ward 1) for separate consideration was a $79,980 contract with Michigan Recreational Construction Inc. for improvements to Placid Way Park. The contract – which involves installing new play equipment as well as park furniture and landscaping – had been recommended for approval by the city's park advisory commission at their March 20, 2012 meeting. The 1.32-acre neighborhood park is located on the city's north side near the larger Dhu Varren Woods Nature Area and Foxfire South Park.

In her brief remarks, Briere described Placid Way as an unusual park that runs between neighborhoods. It's heavily-used by a neighborhood that has many children, she said. And it's a pathway from one neighborhood to another. She was happy see the upgrades happening. Mike Anglin (Ward 5) who serves as one of two city council ex officio non-voting appointees to the park advisory commission, noted the discussion that PAC had had on the park.

Outcome: The council unanimously approved the Placid Way Park renovation contract.

Technical Amendment to Retirement System

Before the council for its final consideration were some amendments to the city ordinance that governs the retirement system. The first change explicitly describes the process that's already used to establish the interest rate in crediting participant contribution accounts. The second change corrects a language error introduced with an ordinance revision made last year, which misstates the methodology for calculating a participant's early retirement benefit. The staff memo accompanying the council resolution indicates that the rates have been calculated correctly, despite the language error.

During the public hearing on the amendments, **Edward Vielmetti** introduced himself as a graduate of the University of Michigan's economics department. He said he didn't know very much about retirement planning. But he said he did know that projections for future returns are notoriously unreliable. In the past, retirement plans that made naive assumptions about future returns have had catastrophic surprises attached to them. He said he could speak to that from some of his own investments over the last 20 years.

Even portfolios that appear to be diversified usually are not, Vielmetti said. He urged the council to do something other than the simplest straight-line projection of future interest rates to project the range of possible outcomes – because a very good year or very bad year early in the cycle can make an enormous difference. Retirement planning is a serious business, he said, and he hoped the city is not taking an oversimplified approach.

Deliberations by the council included brief remarks from Jane Lumm (Ward 2), who characterized the amendments as technical changes that had been requested by the city attorney's office. It's not a change to the actual retirement plan, but rather a cleanup of some language, she said.

Outcome: The council unanimously approved the technical changes to the retirement ordinance.

Communications and Comment

Every city council agenda contains multiple slots for city councilmembers and the city administrator to give updates or make announcements about issues that are coming before the city council. And every meeting typically includes public commentary on subjects not necessarily on the agenda.

Comm/Comm: Greenbelt

Carsten Hohnke (Ward 5) gave an update on the most recent greenbelt advisory commission – as the city council appointee to that body. He briefed his council colleagues on the mid-year financial report the group had received at its last meeting – there's about $6 million left in the millage fund for greenbelt acquisitions, and $4.5 million that's designated for park acquisitions. [For a more detailed look at the April 5, 2012 GAC meeting, see Chronicle coverage: "Greenbelt Commission Briefed on Food Hub," which includes details of the mid-year financial report.] Hohnke also highlighted a deal that the Southeast Michigan Land Conservancy had closed on 100 acres along Prospect Road, a large portion of which is open to the public. The deal was done in partnership with the Ann Arbor greenbelt program. [For coverage, see "Superior Greenway Deal Adds 100 Acres."]

Comm/Comm: Parks Millage

Christopher Taylor (Ward 3) – in his capacity as one of two city council ex officio non-voting appointees to the city park advisory commission – reminded his colleagues of the remaining public outreach activity the city is doing on the parks maintenance and capital improvements millage renewal. [For coverage of the millage proposal, which the city council will likely put on the November 2012 ballot, see "Park Commission Briefed on Millage Renewal."] A public meeting on the renewal of the tax will be held on April 23 from 6:30-7:30 p.m. at Leslie Science and Nature Center. And the final meeting will be April 26 at the Ann Arbor District Library Traverwood branch, Taylor said.

Comm/Comm: UM Wall Street Parking

Sabra Briere (Ward 1) reported that earlier in the day, Jim Kosteva –University of Michigan director of community relations – had informed members of the Ann Arbor city council that UM's board of regents would be voting on April 19 on a proposal to build a 700-space parking structure, to be located between Wall Street and Maiden Lane. [As expected, UM regents approved the project.]

By way of background, the university announced on Feb. 10, 2012 that it was withdrawing from a partnership with the city to build additional parking at the same site where the city hopes to build a transit station – just south of Fuller Road and north of East Medical Center Drive. The Fuller Road site, as a location for additional university parking, had been an alternative to constructing additional parking on Wall Street – which the UM was on course to build up until 2009. The news Briere was reporting, then, reflects the UM's decision to revert to a previous course.

Since before she was first elected [in 2007], Briere said, other members of the city council, the mayor, and other residents had tried to convince regents that while additional parking might be necessary, it should be considered for a satellite location, not a residential street. She said some folks look at the barren parking lot that forms the block between Maiden Lane and Wall Street and say, "Well, who'd want to live there, anyway? Go ahead, shove in a parking structure."

Briere said she'd rather have seen a much more serious effort on the part of UM to improve mass transit. She wanted to encourage the university to develop more aggressive carpooling and alternative transportation options for staff. She wanted to see the number of people reduced who feel that they need to be able to get into their car without walking or waiting. She wanted better consideration of the infrastructure and the environmental impact that the parking structure would have on the community.

For those who think that no one will care and that it's all a wasteland, she asked them to remember, "It's the university that created that wasteland, and the university that wants to make it increasingly inhospitable to the residents who live [there]." She asked the regents of the University of Michigan to remember that good neighbors work together. They could just as easily build parking structures on the north campus or the athletic campus, creating options for those who want to park there, and reducing the number of employees who choose to park and not ride [a play on the term for lots designed for people to arrive, park, then take public transportation to their final destination – called park-and-ride lots.]

Comm/Comm: Agenda Item Titles

Sabra Briere (Ward 1) noted that the length of the titles to agenda items had begun to creep longer and they were not getting clearer as a result. She asked that the 20-word rule on agenda item titles be followed.

By way of illustration, the following title appeared on that night's agenda (137 words):

> An Ordinance to Amend Sections 1:552.1, 1:561, 1:562, 1:565, 1:566, 1.567, 1:568, 1:572 and 1:592 of Chapter 18, Employees Retirement System, Title I of the Code of the City of Ann Arbor to Implement a "Pick-Up" Provision Allowed by Internal Revenue Code 414(h) for Members represented by the IAFF, Local 693 and the Command Officers Association, and Increase the Contribution Level for Members Represented by the Command Officers Association, and to Implement a HELPS provision for Eligible Retired Public Safety Officers, and to Implement an Other Qualified Adult Pop-Up Provision for Members represented by the Ann Arbor Police Officers Association, the Command Officers Association and AFSCME, and to Implement Other Collectively Bargained Changes for Members Represented by the IAFF, Local 693 (Ordinance No. ORD-12-10)

Comm/Comm: Medical Marijuana Dispensary Licenses

Sabra Briere (Ward 1) also told her colleagues that she'd listened to their requests at the council's previous meeting, on April 2, 2012, that medical marijuana dispensary licenses be brought to the council for a vote. However, after further consultation with the city attorney, Stephen Postema, she reported that he's said he would not be able to provide adequate background information to the council on the issue until June. She wanted to let her colleagues know that she had checked, and that Postema was not prepared to move as quickly as she was.

Comm/Comm: Blight Removal

Stephen Kunselman (Ward 3) reported that the city's efforts at blight removal are working in his neighborhood, on Springbrook. He thanked everyone who supports blight removal and the city staff for making it happen.

Comm/Comm: Localized Flooding

During public commentary time, **Ellen Fisher** told the council she was speaking for herself and many of her neighbors in the Churchill Drive area. [It's an area on the west side of the city, east of I-94 and south of Scio Church Road.] She reminded councilmembers that some of them had heard from her before in letters she'd written. That night, she said she wanted to put a face to the message. She told the council that she and her husband had moved into their house on March 23, 1974 – 38 years ago. For 26 years, they had no problems, she reported. However, they'd experienced three localized floods in the neighborhood since 2000, two within the last two years.

Churchill Drive (highlighted in pink) was the subject of public commentary about localized flooding. It's located south of Scio Church Road and east of I-94. This screenshot is from the recent FEMA flood maps adopted by the city, which shows the floodplain (green) and floodway (blue) that exists in the neighborhood, but starting east of Churchill and extending eastward. (Image links to higher resolution file.)

She contended that three specific actions by the city of Ann Arbor were responsible for the flooding – which resulted in her home now serving as the "neighborhood detention pond." First, she said, residential development had been allowed north of Scio Church Road, which caused additional water to flow into the Churchill Downs neighborhood during bad storms. Second, she said, in 1998 the roads in the neighborhood (Wiltshire and Churchill) were resurfaced. But instead of removing older pavement, she said, new asphalt was just laid on top of the old. As a result of laying down new asphalt on top of the old, she described the crown of the road now as above the curb, and the curb as only two inches high. So any time the water gets deeper than two inches on the road during a storm, it's forced off the road into people's houses.

The third city action, she said, was the footing drain disconnection program implemented after the floods of 2000. Since that time, the city has known that the stormwater system in the Churchill Downs area is inadequate, she said. But in 2009 homeowners there had to participate in the footing drain disconnect program.

By way of background, the program requires disconnection of a property's footing drains to the sanitary sewer system, with a new connection made to the stormwater system. The move is meant to prevent the phenomenon of raw sewage backing up into people's basements – due to overloading the sanitary system, which is not designed to deal with the volume of water associated with storms. Fisher's contention is that the stormwater system in the neighborhood is also not adequate to handle the volume of water due to storms.

Fisher continued by describing another flood just a month ago, and showed the council a photo of her house, which she described as an island surrounded by water – 5-6 inches. Storm drain covers were blown off, and geysers shot up five feet into the air, she reported. Water flowed into their basement through the egress windows and up from the sump that was installed through the footing drain disconnect program.

The city of Ann Arbor has attributed this to an "act of god," she said. But she called the flood in her basement an "act of the city." She called on the city to accept responsibility. In the short term, she

Marcia Higgins (Ward 4) as she listens to Ellen Fisher's public comment on localized flooding issues. To Higgins' right (in green shirt) is Margie Teall (Ward 4). Fisher was speaking about flooding in Ward 4.

called for the city to solve the problem of water entering the basement through the sump and to cover the cost of cleanup and mitigation. In the long term, she said, the city needs to address flooding in the neighborhood. She presented the council with a petition signed by several residents of the neighborhood, many of whom were in the audience at city council chambers.

Lowell Fisher, Ellen Fisher's husband, spoke from his wheelchair. He told the council that the floods were taking an emotional and financial toll on him. The value of their home has plummeted, he said. They're afraid to restore their basement – so they're left with a basement they can't use. Because he can't visit all his children, they travel to visit him. They need their basement to host their children and grandchildren. Two years ago a flood cost them $20,000. But their claim for $5,000 in cleanup costs was denied. Nothing was done by the city to prevent another occurrence, he said. He stressed that the floods are not freak storms. There had been storms for the last 26 years prior to the occurrence of flooding problems. He concluded that it's time for the city to take action. More than a dozen people stood in the audience to show support during Fisher's remarks.

Comm/Comm: Smart Meters

Nanci Gerler alluded to a mayoral proclamation that led off the meeting, which established April 22, 2012 as Earth Day in Ann Arbor – the 42nd anniversary of the international observation of Earth Day, which was launched in Ann Arbor on March 10-14, 1970.

Gerler told the council she'd attended the first Earth Day and still has an Earth Day button somewhere in her house. She told the council she appreciated being a part of a community that values the environment and accessibility for those with disabilities. She warned the council that DTE's smart meters had been introduced in Ann Arbor like a Trojan horse, using the guise of sustainability. Only recently had the meters been installed in Ann Arbor, she said, but other parts of the state had a longer experience with them. She told the council that 18 other municipalities have passed resolutions and moratoriums on smart meters, due to questions health safety and invasion of privacy, she said. Why not Ann Arbor? she wondered. Ann Arbor is usually progressive on such issues.

Gerler described how DTE is making no exceptions, and does not give consumers the right to opt out. She said that she'd been told by the Michigan Public Service Commission that if she refuses to allow installation, she could have her electricity shut off, even if she pays in a timely fashion. She offered to work with councilmembers to bring them up to speed on the issue. She asked councilmembers to help her get the message out.

Darren Schmidt introduced himself as the president and CEO of the Nutritional Healing Center of Ann Arbor. He described how the center helps people improve their health through nutrition. He said that a few years ago he became aware that some of the fatigue, memory loss, sleep disorders, and illnesses including Parkinson's Disease could be attributed to "dirty electricity" and magnetic fields. [The council's agenda included a mayoral proclamation establishing April as Parkinson's Disease Awareness Month.] He showed the council a book titled "Dirty Electricity," which that concluded electromagnetic frequencies and radio frequencies are the No. 1 cause of cancer in the U.S. He cited another book, titled "Zapped," that provides ways to avoid electromagnetic pollution.

Schmidt said 3-5% of the population are extremely sensitive to magnetic fields and 35-50% are somewhat sensitive, but may not know it. Most doctors don't know anything about this condition, he said. He had stumbled across it because his patients need the best care possible and they're not constrained by pharmaceutical requirements. He also showed the council a letter from the American Academy of Environmental Medicine. The president-elect of that organization, he said, is Amy Dean, who's a doctor of osteopathic medicine (D.O.) and based in Ann Arbor. The AAEM on April 12 released its position paper on electromagnetic fields and radio frequency health effects, and that paper had called for immediate caution on installation of "smart meters." He compared installing "smart meters" in neighborhoods to "living in a microwave" that can't be turned off.

Comm/Comm: Affordable Services for Most Vulnerable

Thomas Partridge called on the council to fund services for the most vulnerable – from disabled citizens, to senior citizens, to the middle class – those who need job opportunities and access to public transportation to get to those jobs. He called for the nomination of Barack Obama for re-election as president of the United States.

Present: Jane Lumm, Mike Anglin, Margie Teall, Sabra Briere, Sandi Smith, Tony Derezinski, Stephen Kunselman, Marcia Higgins, John Hieftje, Christopher Taylor, Carsten Hohnke.

Next council meeting: Monday, May 7, 2012 at 7 p.m. in the second-floor council chambers at city hall, 301 E. Huron. [confirm date]

The Chronicle could not survive without regular voluntary subscriptions to support our coverage of public bodies like the Ann Arbor city council. Did the airport runway extension study take into account the donut imbalance that will result from having a Tim Horton's off the northeast end of the runway and no donuts off the southwest end?

On a more serious note, I was surprised to read in the Detroit Free Press that DTE has asked for a rate increase to pay for the new "smart" meters. I thought the whole idea was that they'd be cheaper because meter readers would no longer have to be sent out. If they end up costing us more than the old meters, what's the point?

2. BY TEACHERPATTI
APRIL 21, 2012 at 11:16 pm | PERMALINK

Um, is that stuff about the smart meters and cancer and that true? Cuz I'm kind of worried.

I'm not clear on the biosolids contract that was approved. Is the City PAYING $514K to have biosolids spread on farm fields, or is the City being PAID $514K for providing this "fertilizer?"

If the City is paying, how much more or less is this cost per gallon ($0.0321) than the cost of landfilling it?

4. BY DAVE ASKINS
APRIL 22, 2012 at 11:21 am | PERMALINK

Re: [3] It's the city's cost.

Assuming a weight of about 8 pounds a gallon, that works out to ((US$ 0.0321) / 8) * 2000 = 8.02500 U.S. dollars per ton.

From minutes of a March 2012 meeting of the "organics subcommittee" of the solid waste unit (comparing the cost of processing organics versus landfilling them) it looks like the city currently pays $26 per ton to put material in a landfill.

Thanks, Dave.

While you were looking into that, I checked the web to see if Bio Tech Agronomics was affiliated with WeCare Organics, the firm running the City's compost facility. I could not find any connection between the two in the brief time I spent on it.

WeCare Organics blends biosolids into compost in other cities, and has affiliates that transport biosolids and make fertilizer products from blends of compost and biosolids. Some people expressed concern that WeCare would introduce biosolids into Ann Arbor's compost, but assurances were provided around the Council table that this would not happen and as far as I know, it hasn't happened.

The "student press" alluded to in my commentary on minor-in-possession laws can be found starting here:

[link]

with this pull quote

"To combat the potential issue at the University, members of the Central Student Government — formerly known as the Michigan Student Assembly — are working on a proposal to implement medical amnesty at the University, a policy that would protect students from receiving an MIP if they call for alcohol-related medical attention for another person while also under the influence."

7. BY LIEBEZEIT
APRIL 23, 2012 at 5:14 am | PERMALINK

"He said that a few years ago he became aware that some of the fatigue, memory loss, sleep disorders, and illnesses including Parkinson's Disease could be attributed to "dirty electricity" and magnetic fields."

Hilarious…classic Ann Arbor.

If you are concerned about the electromagnetic fields from your electric service, there is a simple solution. Call up DTE and ask them to remove the meter.

9. BY DAVE ASKINS
APRIL 23, 2012 at 10:18 am | PERMALINK

Re: [8] Calling DTE and asking them to remove the meter.

Our smart meter was installed a few weeks ago. I called customer service just now to test whether a simple phone call could do the trick. According to the customer service representative I talked to, there's currently no provision for opting out either before or after the fact. However, she indicated that talks are taking place between DTE and the Michigan Public Service Commission about providing customers the ability to opt out. To be clear, I'm not actually interested in having the "smart meter" removed; I was just following up on Jim's suggestion.

10. BY DAVE ASKINS
APRIL 23, 2012 at 10:51 am | PERMALINK

And to follow up on [9], the "talks" that are taking place between DTE and MPSC can be more precisely described as follows, based on a conversation with MPSC just now.

On Jan. 12, MPSC issued an order requiring utilities to file information with MPSC about "smart meter" rollout plans, including estimated cost, funding, estimated savings, and non-monetary benefits, scientific information, and whether an opt out would be provided (included how costs associated with opt outs might be recovered.) The deadline for that filing was March 16, which DTE met. Public comment on that was open through April 16. The information filed in response to MPSC's order will all be complied into a report, supplemented with independent review of relevant literature, and produced by June 29. At that point, MPSC commissioners will have a document on the basis of which they could issue further orders or weigh future rate cases brought by DTE before the MPSC.

Also in the mix is pending House Bill 5439, which would legislatively provide for an opt-out by consumers and regulate how data collected by the meters is used.

11. BY JIM REES
APRIL 23, 2012 at 1:03 pm | PERMALINK

Dave, you misunderstood me. You are perfectly within your rights to have the meter removed, and if DTE won't do it, you can remove it yourself (safely, please!). You will then be left with no electromagnetic fields in your house from your DTE electric service. You will also have no electricity.

12. BY DAVE ASKINS
APRIL 23, 2012 at 1:09 pm | PERMALINK

Re: [11] Ah! Yes, I did misunderstand you.

Exhibit 21

FAA
Airports

Grant Assurances
Airport Sponsors

A. General.

1. These assurances shall be complied with in the performance of grant agreements for airport development, airport planning, and noise compatibility program grants for airport sponsors.

2. These assurances are required to be submitted as part of the project application by sponsors requesting funds under the provisions of Title 49, U.S.C., subtitle VII, as amended. As used herein, the term "public agency sponsor" means a public agency with control of a public-use airport; the term "private sponsor" means a private owner of a public-use airport; and the term "sponsor" includes both public agency sponsors and private sponsors.

3. Upon acceptance of this grant offer by the sponsor, these assurances are incorporated in and become part of this grant agreement.

B. Duration and Applicability.

1. **Airport development or Noise Compatibility Program Projects Undertaken by a Public Agency Sponsor**. The terms, conditions and assurances of this grant agreement shall remain in full force and effect throughout the useful life of the facilities developed or equipment acquired for an airport development or noise compatibility program project, or throughout the useful life of the project items installed within a facility under a noise compatibility program project, but in any event not to exceed twenty (20) years from the date of acceptance of a grant offer of Federal funds for the project. However, there shall be no limit on the duration of the assurances regarding Exclusive Rights and Airport Revenue so long as the airport is used as an airport. There shall be no limit on the duration of the terms, conditions, and assurances with respect to real property acquired with federal funds. Furthermore, the duration of the Civil Rights assurance shall be specified in the assurances.

2. **Airport Development or Noise Compatibility Projects Undertaken by a Private Sponsor**. The preceding paragraph 1 also applies to a private sponsor except that the useful life of project items installed within a facility or the useful life of the facilities developed or equipment acquired under an airport development or noise compatibility program project shall be no less than ten (10) years from the date of acceptance of Federal aid for the project.

3. **Airport Planning Undertaken by a Sponsor.** Unless otherwise specified in this grant agreement, only Assurances 1, 2, 3, 5, 6, 13, 18, 30, 32, 33, and 34 in section C apply to planning projects. The terms, conditions, and assurances of this grant agreement shall remain in full force and effect during the life of the project.

C. **Sponsor Certification.** The sponsor hereby assures and certifies, with respect to this grant that:

1. **General Federal Requirements.** It will comply with all applicable Federal laws, regulations, executive orders, policies, guidelines, and requirements as they relate to the application, acceptance and use of Federal funds for this project including but not limited to the following:

Federal Legislation

a. Title 49, U.S.C., subtitle VII, as amended.
b. Davis-Bacon Act - 40 U.S.C. 276(a), et seq.[1]
c. Federal Fair Labor Standards Act - 29 U.S.C. 201, et seq.
d. Hatch Act – 5 U.S.C. 1501, et seq.[2]
e. Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 Title 42 U.S.C. 4601, et seq.[1 2]
f. National Historic Preservation Act of 1966 - Section 106 - 16 U.S.C. 470(f).[1]
g. Archeological and Historic Preservation Act of 1974 - 16 U.S.C. 469 through 469c.[1]
h. Native Americans Grave Repatriation Act - 25 U.S.C. Section 3001, et seq.
i. Clean Air Act, P.L. 90-148, as amended.
j. Coastal Zone Management Act, P.L. 93-205, as amended.
k. Flood Disaster Protection Act of 1973 - Section 102(a) - 42 U.S.C. 4012a.[1]
l. Title 49, U.S.C., Section 303, (formerly known as Section 4(f))
m. Rehabilitation Act of 1973 - 29 U.S.C. 794.
n. Civil Rights Act of 1964 - Title VI - 42 U.S.C. 2000d through d-4.
o. Age Discrimination Act of 1975 - 42 U.S.C. 6101, et seq.
p. American Indian Religious Freedom Act, P.L. 95-341, as amended.
q. Architectural Barriers Act of 1968 -42 U.S.C. 4151, et seq.[1]
r. Power plant and Industrial Fuel Use Act of 1978 - Section 403- 2 U.S.C. 8373.[1]
s. Contract Work Hours and Safety Standards Act - 40 U.S.C. 327, et seq.[1]
t. Copeland Anti kickback Act - 18 U.S.C. 874.1
u. National Environmental Policy Act of 1969 - 42 U.S.C. 4321, et seq.[1]
v. Wild and Scenic Rivers Act, P.L. 90-542, as amended.
w. Single Audit Act of 1984 - 31 U.S.C. 7501, et seq.[2]
x. Drug-Free Workplace Act of 1988 - 41 U.S.C. 702 through 706.

Executive Orders

Executive Order 11246 - Equal Employment Opportunity[1]
Executive Order 11990 - Protection of Wetlands
Executive Order 11998 – Flood Plain Management
Executive Order 12372 - Intergovernmental Review of Federal Programs
Executive Order 12699 - Seismic Safety of Federal and Federally Assisted New Building Construction[1]
Executive Order 12898 - Environmental Justice

Federal Regulations

a. 14 CFR Part 13 - Investigative and Enforcement Procedures.
b. 14 CFR Part 16 - Rules of Practice For Federally Assisted Airport Enforcement Proceedings.
c. 14 CFR Part 150 - Airport noise compatibility planning.
d. 29 CFR Part 1 - Procedures for predetermination of wage rates.[1]
e. 29 CFR Part 3 - Contractors and subcontractors on public building or public work financed in whole or part by loans or grants from the United States.[1]
f. 29 CFR Part 5 - Labor standards provisions applicable to contracts covering federally financed and assisted construction (also labor standards provisions applicable to non-construction contracts subject to the Contract Work Hours and Safety Standards Act).[1]
g. 41 CFR Part 60 - Office of Federal Contract Compliance Programs, Equal Employment Opportunity, Department of Labor (Federal and federally assisted contracting requirements).[1]
h. 49 CFR Part 18 - Uniform administrative requirements for grants and cooperative agreements to state and local governments.[3]
i. 49 CFR Part 20 - New restrictions on lobbying.
j. 49 CFR Part 21 - Nondiscrimination in federally-assisted programs of the Department of Transportation - effectuation of Title VI of the Civil Rights Act of 1964.
k. 49 CFR Part 23 - Participation by Disadvantage Business Enterprise in Airport Concessions.
l. 49 CFR Part 24 - Uniform relocation assistance and real property acquisition for Federal and federally assisted programs.[1 2]
m. 49 CFR Part 26 – Participation By Disadvantaged Business Enterprises in Department of Transportation Programs.
n. 49 CFR Part 27 - Nondiscrimination on the basis of handicap in programs and activities receiving or benefiting from Federal financial assistance.[1]
o. 49 CFR Part 29 – Government wide debarment and suspension (nonprocurement) and government wide requirements for drug-free workplace (grants).
p. 49 CFR Part 30 - Denial of public works contracts to suppliers of goods and services of countries that deny procurement market access to U.S. contractors.

q. 49 CFR Part 41 - Seismic safety of Federal and federally assisted or regulated new building construction.[1]

Office of Management and Budget Circulars

a. A-87 - Cost Principles Applicable to Grants and Contracts with State and Local Governments.
b. A-133 - Audits of States, Local Governments, and Non-Profit Organizations

[1] These laws do not apply to airport planning sponsors.
[2] These laws do not apply to private sponsors.
[3] 49 CFR Part 18 and OMB Circular A-87 contain requirements for State and Local Governments receiving Federal assistance. Any requirement levied upon State and Local Governments by this regulation and circular shall also be applicable to private sponsors receiving Federal assistance under Title 49, United States Code.

Specific assurances required to be included in grant agreements by any of the above laws, regulations or circulars are incorporated by reference in this grant agreement.

2. Responsibility and Authority of the Sponsor.

a. **Public Agency Sponsor:** It has legal authority to apply for this grant, and to finance and carry out the proposed project; that a resolution, motion or similar action has been duly adopted or passed as an official act of the applicant's governing body authorizing the filing of the application, including all understandings and assurances contained therein, and directing and authorizing the person identified as the official representative of the applicant to act in connection with the application and to provide such additional information as may be required.
b. **Private Sponsor:** It has legal authority to apply for this grant and to finance and carry out the proposed project and comply with all terms, conditions, and assurances of this grant agreement. It shall designate an official representative and shall in writing direct and authorize that person to file this application, including all understandings and assurances contained therein; to act in connection with this application; and to provide such additional information as may be required.

3. Sponsor Fund Availability. It has sufficient funds available for that portion of the project costs which are not to be paid by the United States. It has sufficient funds available to assure operation and maintenance of items funded under this grant agreement which it will own or control.

4. Good Title.

a. It, a public agency or the Federal government, holds good title, satisfactory to the Secretary, to the landing area of the airport or site thereof, or will give assurance satisfactory to the Secretary that good title will be acquired.

b. For noise compatibility program projects to be carried out on the property of the sponsor, it holds good title satisfactory to the Secretary to that portion of the property upon which Federal funds will be expended or will give assurance to the Secretary that good title will be obtained.

5. Preserving Rights and Powers.

a. It will not take or permit any action which would operate to deprive it of any of the rights and powers necessary to perform any or all of the terms, conditions, and assurances in this grant agreement without the written approval of the Secretary, and will act promptly to acquire, extinguish or modify any outstanding rights or claims of right of others which would interfere with such performance by the sponsor. This shall be done in a manner acceptable to the Secretary.

b. It will not sell, lease, encumber, or otherwise transfer or dispose of any part of its title or other interests in the property shown on Exhibit A to this application or, for a noise compatibility program project, that portion of the property upon which Federal funds have been expended, for the duration of the terms, conditions, and assurances in this grant agreement without approval by the Secretary. If the transferee is found by the Secretary to be eligible under Title 49, United States Code, to assume the obligations of this grant agreement and to have the power, authority, and financial resources to carry out all such obligations, the sponsor shall insert in the contract or document transferring or disposing of the sponsor's interest, and make binding upon the transferee all of the terms, conditions, and assurances contained in this grant agreement.

c. For all noise compatibility program projects which are to be carried out by another unit of local government or are on property owned by a unit of local government other than the sponsor, it will enter into an agreement with that government. Except as otherwise specified by the Secretary, that agreement shall obligate that government to the same terms, conditions, and assurances that would be applicable to it if it applied directly to the FAA for a grant to undertake the noise compatibility program project. That agreement and changes thereto must be satisfactory to the Secretary. It will take steps to enforce this agreement against the local government if there is substantial non-compliance with the terms of the agreement.

d. For noise compatibility program projects to be carried out on privately owned property, it will enter into an agreement with the owner of that property which includes provisions specified by the Secretary. It will take steps to enforce this agreement against the property owner whenever there is substantial non-compliance with the terms of the agreement.

e. If the sponsor is a private sponsor, it will take steps satisfactory to the Secretary to ensure that the airport will continue to function as a public-use airport in accordance with these assurances for the duration of these assurances.

f. If an arrangement is made for management and operation of the airport by any agency or person other than the sponsor or an employee of the sponsor, the sponsor will reserve sufficient rights and authority to insure that the airport will be operated and maintained in accordance Title 49, United States Code, the regulations and the terms, conditions and assurances in this grant agreement and shall insure that such arrangement also requires compliance therewith.

g. Sponsors of commercial service airports will not permit or enter into any arrangement that results in permission for the owner or tenant of a property used as a residence, or zoned for residential use, to taxi an aircraft between that property and any location on airport. Sponsors of general aviation airports entering into any arrangement that results in permission for the owner of residential real property adjacent to or near the airport must comply with the requirements of Sec. 136 of Public Law 112-95 and the sponsor assurances.

6. **Consistency with Local Plans.** The project is reasonably consistent with plans (existing at the time of submission of this application) of public agencies that are authorized by the State in which the project is located to plan for the development of the area surrounding the airport.

7. **Consideration of Local Interest.** It has given fair consideration to the interest of communities in or near where the project may be located.

8. **Consultation with Users.** In making a decision to undertake any airport development project under Title 49, United States Code, it has undertaken reasonable consultations with affected parties using the airport at which project is proposed.

9. **Public Hearings.** In projects involving the location of an airport, an airport runway, or a major runway extension, it has afforded the opportunity for public hearings for the purpose of considering the economic, social, and environmental effects of the airport or runway location and its consistency with goals and objectives of such planning as has been carried out by the community and it shall, when requested by the Secretary, submit a copy of the transcript of such hearings to the Secretary. Further, for such projects, it has on its management board either voting representation from the communities where the project is located or has advised the communities that they have the right to petition the Secretary concerning a proposed project.

10. **Air and Water Quality Standards.** In projects involving airport location, a major runway extension, or runway location it will provide for the Governor of the state in which the project is located to certify in writing to the Secretary that the project will be located, designed, constructed, and operated so as to comply with applicable air and water quality standards. In any case where such standards have not been approved and where applicable air and water quality standards have been promulgated by the Administrator of the Environmental Protection Agency, certification shall be obtained from such Administrator. Notice of certification or refusal to certify shall be provided within sixty days after the project application has been received by the Secretary.

11. **Pavement Preventive Maintenance**. With respect to a project approved after January 1, 1995, for the replacement or reconstruction of pavement at the airport, it assures or certifies that it has implemented an effective airport pavement maintenance-management program and it assures that it will use such program for the useful life of any pavement constructed, reconstructed or repaired with Federal financial assistance at the airport. It will provide such reports on pavement condition and pavement management programs as the Secretary determines may be useful.

12. **Terminal Development Prerequisites.** For projects which include terminal development at a public use airport, as defined in Title 49, it has, on the date of submittal of the project grant application, all the safety equipment required for certification of such airport under section 44706 of Title 49, United States Code, and all the security equipment required by rule or regulation, and has provided for access to the passenger enplaning and deplaning area of such airport to passengers enplaning and deplaning from aircraft other than air carrier aircraft.

13. **Accounting System, Audit, and Record Keeping Requirements**.

    a. It shall keep all project accounts and records which fully disclose the amount and disposition by the recipient of the proceeds of this grant, the total cost of the project in connection with which this grant is given or used, and the amount or nature of that portion of the cost of the project supplied by other sources, and such other financial records pertinent to the project. The accounts and records shall be kept in accordance with an accounting system that will facilitate an effective audit in accordance with the Single Audit Act of 1984.

    b. It shall make available to the Secretary and the Comptroller General of the United States, or any of their duly authorized representatives, for the purpose of audit and examination, any books, documents, papers, and records of the recipient that are pertinent to this grant. The Secretary may require that an appropriate audit be conducted by a recipient. In any case in which an independent audit is made of the accounts of a sponsor relating to the disposition of the proceeds of a grant or relating to the project in connection with which this grant was given or used, it shall file a certified copy of such audit with the Comptroller General of the United States not later than six (6) months following the close of the fiscal year for which the audit was made.

14. **Minimum Wage Rates.** It shall include, in all contracts in excess of $2,000 for work on any projects funded under this grant agreement which involve labor, provisions establishing minimum rates of wages, to be predetermined by the Secretary of Labor, in accordance with the Davis-Bacon Act, as amended (40 U.S.C. 276a-276a-5), which contractors shall pay to skilled and unskilled labor, and such minimum rates shall be stated in the invitation for bids and shall be included in proposals or bids for the work.

15. **Veteran's Preference.** It shall include in all contracts for work on any project funded under this grant agreement which involve labor, such provisions as are necessary to insure that, in the employment of labor (except in executive, administrative, and supervisory positions), preference shall be given to Vietnam

era veterans, Persian Gulf veterans, Afghanistan-Iraq war veterans, disabled veterans, and small business concerns owned and controlled by disabled veterans as defined in Section 47112 of Title 49, United States Code. However, this preference shall apply only where the individuals are available and qualified to perform the work to which the employment relates.

16. **Conformity to Plans and Specifications.** It will execute the project subject to plans, specifications, and schedules approved by the Secretary. Such plans, specifications, and schedules shall be submitted to the Secretary prior to commencement of site preparation, construction, or other performance under this grant agreement, and, upon approval of the Secretary, shall be incorporated into this grant agreement. Any modification to the approved plans, specifications, and schedules shall also be subject to approval of the Secretary, and incorporated into this grant agreement.

17. **Construction Inspection and Approval.** It will provide and maintain competent technical supervision at the construction site throughout the project to assure that the work conforms to the plans, specifications, and schedules approved by the Secretary for the project. It shall subject the construction work on any project contained in an approved project application to inspection and approval by the Secretary and such work shall be in accordance with regulations and procedures prescribed by the Secretary. Such regulations and procedures shall require such cost and progress reporting by the sponsor or sponsors of such project as the Secretary shall deem necessary.

18. **Planning Projects.** In carrying out planning projects:

    a. It will execute the project in accordance with the approved program narrative contained in the project application or with the modifications similarly approved.
    b. It will furnish the Secretary with such periodic reports as required pertaining to the planning project and planning work activities.
    c. It will include in all published material prepared in connection with the planning project a notice that the material was prepared under a grant provided by the United States.
    d. It will make such material available for examination by the public, and agrees that no material prepared with funds under this project shall be subject to copyright in the United States or any other country.
    e. It will give the Secretary unrestricted authority to publish, disclose, distribute, and otherwise use any of the material prepared in connection with this grant.
    f. It will grant the Secretary the right to disapprove the sponsor's employment of specific consultants and their subcontractors to do all or any part of this project as well as the right to disapprove the proposed scope and cost of professional services.
    g. It will grant the Secretary the right to disapprove the use of the sponsor's employees to do all or any part of the project.
    h. It understands and agrees that the Secretary's approval of this project grant or the Secretary's approval of any planning material developed as part of

this grant does not constitute or imply any assurance or commitment on the part of the Secretary to approve any pending or future application for a Federal airport grant.

19. Operation and Maintenance.

a. The airport and all facilities which are necessary to serve the aeronautical users of the airport, other than facilities owned or controlled by the United States, shall be operated at all times in a safe and serviceable condition and in accordance with the minimum standards as may be required or prescribed by applicable Federal, state and local agencies for maintenance and operation. It will not cause or permit any activity or action thereon which would interfere with its use for airport purposes. It will suitably operate and maintain the airport and all facilities thereon or connected therewith, with due regard to climatic and flood conditions. Any proposal to temporarily close the airport for non-aeronautical purposes must first be approved by the Secretary. In furtherance of this assurance, the sponsor will have in effect arrangements for-

1) Operating the airport's aeronautical facilities whenever required;
2) Promptly marking and lighting hazards resulting from airport conditions, including temporary conditions; and
3) Promptly notifying airmen of any condition affecting aeronautical use of the airport. Nothing contained herein shall be construed to require that the airport be operated for aeronautical use during temporary periods when snow, flood or other climatic conditions interfere with such operation and maintenance. Further, nothing herein shall be construed as requiring the maintenance, repair, restoration, or replacement of any structure or facility which is substantially damaged or destroyed due to an act of God or other condition or circumstance beyond the control of the sponsor.

b. It will suitably operate and maintain noise compatibility program items that it owns or controls upon which Federal funds have been expended.

20. Hazard Removal and Mitigation. It will take appropriate action to assure that such terminal airspace as is required to protect instrument and visual operations to the airport (including established minimum flight altitudes) will be adequately cleared and protected by removing, lowering, relocating, marking, or lighting or otherwise mitigating existing airport hazards and by preventing the establishment or creation of future airport hazards.

21. Compatible Land Use. It will take appropriate action, to the extent reasonable, including the adoption of zoning laws, to restrict the use of land adjacent to or in the immediate vicinity of the airport to activities and purposes compatible with normal airport operations, including landing and takeoff of aircraft. In addition, if the project is for noise compatibility program implementation, it will not cause or permit any change in land use, within its jurisdiction, that will reduce its compatibility, with respect to the airport, of the noise compatibility program measures upon which Federal funds have been expended.

22. Economic Nondiscrimination.

a. It will make the airport available as an airport for public use on reasonable terms and without unjust discrimination to all types, kinds and classes of aeronautical activities, including commercial aeronautical activities offering services to the public at the airport.

b. In any agreement, contract, lease, or other arrangement under which a right or privilege at the airport is granted to any person, firm, or corporation to conduct or to engage in any aeronautical activity for furnishing services to the public at the airport, the sponsor will insert and enforce provisions requiring the contractor to-

  1) furnish said services on a reasonable, and not unjustly discriminatory, basis to all users thereof, and

  2) charge reasonable, and not unjustly discriminatory, prices for each unit or service, provided that the contractor may be allowed to make reasonable and nondiscriminatory discounts, rebates, or other similar types of price reductions to volume purchasers.

c. Each fixed-based operator at the airport shall be subject to the same rates, fees, rentals, and other charges as are uniformly applicable to all other fixed-based operators making the same or similar uses of such airport and utilizing the same or similar facilities.

d. Each air carrier using such airport shall have the right to service itself or to use any fixed-based operator that is authorized or permitted by the airport to serve any air carrier at such airport.

e. Each air carrier using such airport (whether as a tenant, non tenant, or subtenant of another air carrier tenant) shall be subject to such nondiscriminatory and substantially comparable rules, regulations, conditions, rates, fees, rentals, and other charges with respect to facilities directly and substantially related to providing air transportation as are applicable to all such air carriers which make similar use of such airport and utilize similar facilities, subject to reasonable classifications such as tenants or non tenants and signatory carriers and non signatory carriers. Classification or status as tenant or signatory shall not be unreasonably withheld by any airport provided an air carrier assumes obligations substantially similar to those already imposed on air carriers in such classification or status.

f. It will not exercise or grant any right or privilege which operates to prevent any person, firm, or corporation operating aircraft on the airport from performing any services on its own aircraft with its own employees [including, but not limited to maintenance, repair, and fueling] that it may choose to perform.

g. In the event the sponsor itself exercises any of the rights and privileges referred to in this assurance, the services involved will be provided on the same conditions as would apply to the furnishing of such services by commercial aeronautical service providers authorized by the sponsor under these provisions.

h. The sponsor may establish such reasonable, and not unjustly discriminatory, conditions to be met by all users of the airport as may be necessary for the safe and efficient operation of the airport.

i. The sponsor may prohibit or limit any given type, kind or class of aeronautical use of the airport if such action is necessary for the safe operation of the airport or necessary to serve the civil aviation needs of the public.

23. **Exclusive Rights.** It will permit no exclusive right for the use of the airport by any person providing, or intending to provide, aeronautical services to the public. For purposes of this paragraph, the providing of the services at an airport by a single fixed-based operator shall not be construed as an exclusive right if both of the following apply:

a. It would be unreasonably costly, burdensome, or impractical for more than one fixed-based operator to provide such services, and

b. If allowing more than one fixed-based operator to provide such services would require the reduction of space leased pursuant to an existing agreement between such single fixed-based operator and such airport. It further agrees that it will not, either directly or indirectly, grant or permit any person, firm, or corporation, the exclusive right at the airport to conduct any aeronautical activities, including, but not limited to charter flights, pilot training, aircraft rental and sightseeing, aerial photography, crop dusting, aerial advertising and surveying, air carrier operations, aircraft sales and services, sale of aviation petroleum products whether or not conducted in conjunction with other aeronautical activity, repair and maintenance of aircraft, sale of aircraft parts, and any other activities which because of their direct relationship to the operation of aircraft can be regarded as an aeronautical activity, and that it will terminate any exclusive right to conduct an aeronautical activity now existing at such an airport before the grant of any assistance under Title 49, United States Code.

24. **Fee and Rental Structure.** It will maintain a fee and rental structure for the facilities and services at the airport which will make the airport as self-sustaining as possible under the circumstances existing at the particular airport, taking into account such factors as the volume of traffic and economy of collection. No part of the Federal share of an airport development, airport planning or noise compatibility project for which a grant is made under Title 49, United States Code, the Airport and Airway Improvement Act of 1982, the Federal Airport Act or the Airport and Airway Development Act of 1970 shall be included in the rate basis in establishing fees, rates, and charges for users of that airport.

25. **Airport Revenues.**

a. All revenues generated by the airport and any local taxes on aviation fuel established after December 30, 1987, will be expended by it for the capital or operating costs of the airport; the local airport system; or other local facilities which are owned or operated by the owner or operator of the airport and which are directly and substantially related to the actual air transportation of passengers or property; or for noise mitigation purposes on or off the airport. The following exceptions apply to this paragraph:

1) If covenants or assurances in debt obligations issued before September 3, 1982, by the owner or operator of the airport, or provisions enacted before September 3, 1982, in governing statutes controlling the owner or operator's financing, provide for the use of the revenues from any of the airport owner or operator's facilities, including the airport, to support not only the airport but also the airport owner or operator's general debt obligations or other facilities, then this limitation on the use of all revenues generated by the airport (and, in the case of a public airport, local taxes on aviation fuel) shall not apply.

2) If the Secretary approves the sale of a privately owned airport to a public sponsor and provides funding for any portion of the public sponsor's acquisition of land, this limitation on the use of all revenues generated by the sale shall not apply to certain proceeds from the sale. This is conditioned on repayment to the Secretary by the private owner of an amount equal to the remaining unamortized portion (amortized over a 20-year period) of any airport improvement grant made to the private owner for any purpose other than land acquisition on or after October 1, 1996, plus an amount equal to the federal share of the current fair market value of any land acquired with an airport improvement grant made to that airport on or after October 1, 1996.

3) Certain revenue derived from or generated by mineral extraction, production, lease, or other means at a general aviation airport (as defined at Section 47102 of title 49 United States Code), if the FAA determines the airport sponsor meets the requirements set forth in Sec. 813 of Public Law 112-95.

b. As part of the annual audit required under the Single Audit Act of 1984, the sponsor will direct that the audit will review, and the resulting audit report will provide an opinion concerning, the use of airport revenue and taxes in paragraph (a), and indicating whether funds paid or transferred to the owner or operator are paid or transferred in a manner consistent with Title 49, United States Code and any other applicable provision of law, including any regulation promulgated by the Secretary or Administrator.

c. Any civil penalties or other sanctions will be imposed for violation of this assurance in accordance with the provisions of Section 47107 of Title 49, United States Code.

26. Reports and Inspections. It will:

a. submit to the Secretary such annual or special financial and operations reports as the Secretary may reasonably request and make such reports available to the public; make available to the public at reasonable times and places a report of the airport budget in a format prescribed by the Secretary;

b. for airport development projects, make the airport and all airport records and documents affecting the airport, including deeds, leases, operation and use agreements, regulations and other instruments, available for inspection by any duly authorized agent of the Secretary upon reasonable request;

c. for noise compatibility program projects, make records and documents relating to the project and continued compliance with the terms, conditions, and assurances of this grant agreement including deeds, leases, agreements, regulations, and other instruments, available for inspection by any duly authorized agent of the Secretary upon reasonable request; and

d. in a format and time prescribed by the Secretary, provide to the Secretary and make available to the public following each of its fiscal years, an annual report listing in detail:

   1) all amounts paid by the airport to any other unit of government and the purposes for which each such payment was made; and

   2) all services and property provided by the airport to other units of government and the amount of compensation received for provision of each such service and property.

27. Use by Government Aircraft. It will make available all of the facilities of the airport developed with Federal financial assistance and all those usable for landing and takeoff of aircraft to the United States for use by Government aircraft in common with other aircraft at all times without charge, except, if the use by Government aircraft is substantial, charge may be made for a reasonable share, proportional to such use, for the cost of operating and maintaining the facilities used. Unless otherwise determined by the Secretary, or otherwise agreed to by the sponsor and the using agency, substantial use of an airport by Government aircraft will be considered to exist when operations of such aircraft are in excess of those which, in the opinion of the Secretary, would unduly interfere with use of the landing areas by other authorized aircraft, or during any calendar month that –

a. Five (5) or more Government aircraft are regularly based at the airport or on land adjacent thereto; or

b. The total number of movements (counting each landing as a movement) of Government aircraft is 300 or more, or the gross accumulative weight of Government aircraft using the airport (the total movement of Government aircraft multiplied by gross weights of such aircraft) is in excess of five million pounds.

28. Land for Federal Facilities. It will furnish without cost to the Federal Government for use in connection with any air traffic control or air navigation activities, or weather-reporting and communication activities related to air traffic control, any areas of land or water, or estate therein, or rights in buildings of the sponsor as the Secretary considers necessary or desirable for construction, operation, and maintenance at Federal expense of space or facilities for such purposes. Such areas or any portion thereof will be made available as provided herein within four months after receipt of a written request from the Secretary.

29. Airport Layout Plan.

a. It will keep up to date at all times an airport layout plan of the airport showing (1) boundaries of the airport and all proposed additions thereto, together with the boundaries of all offsite areas owned or controlled by the sponsor for airport purposes and proposed additions thereto; (2) the location and nature of all existing and proposed airport facilities and structures (such as runways, taxiways, aprons, terminal buildings, hangars and roads), including all proposed extensions and reductions of existing airport facilities; (3) the location of all existing and proposed nonaviation areas and of all existing improvements thereon; and (4) all proposed and existing access points used to taxi aircraft across the airport's property boundary. Such airport layout plans and each amendment, revision, or modification thereof, shall be subject to the approval of the Secretary which approval shall be evidenced by the signature of a duly authorized representative of the Secretary on the face of the airport layout plan. The sponsor will not make or permit any changes or alterations in the airport or any of its facilities which are not in conformity with the airport layout plan as approved by the Secretary and which might, in the opinion of the Secretary, adversely affect the safety, utility or efficiency of the airport.

b. If a change or alteration in the airport or the facilities is made which the Secretary determines adversely affects the safety, utility, or efficiency of any federally owned, leased, or funded property on or off the airport and which is not in conformity with the airport layout plan as approved by the Secretary, the owner or operator will, if requested, by the Secretary (1) eliminate such adverse effect in a manner approved by the Secretary; or (2) bear all costs of relocating such property (or replacement thereof) to a site acceptable to the Secretary and all costs of restoring such property (or replacement thereof) to the level of safety, utility, efficiency, and cost of operation existing before the unapproved change in the airport or its facilities except in the case of a relocation or replacement of an existing airport facility due to a change in the Secretary's design standards beyond the control of the airport sponsor.

30. Civil Rights. It will comply with such rules as are promulgated to assure that no person shall, on the grounds of race, creed, color, national origin, sex, age, or handicap be excluded from participating in any activity conducted with or benefiting from funds received from this grant. This assurance obligates the sponsor for the period during which Federal financial assistance is extended to the program, except where Federal financial assistance is to provide, or is in the form of personal property or real property or interest therein or structures or improvements thereon in which case the assurance obligates the sponsor or any transferee for the longer of the following periods: (a) the period during which the property is used for a purpose for which Federal financial assistance is extended, or for another purpose involving the provision of similar services or benefits, or

(b) the period during which the sponsor retains ownership or possession of the property.

31. Disposal of Land.

a. For land purchased under a grant for airport noise compatibility purposes, including land serving as a noise buffer, it will dispose of the land, when the land is no longer needed for such purposes, at fair market value, at the earliest practicable time. That portion of the proceeds of such disposition which is proportionate to the United States' share of acquisition of such land will be, at the discretion of the Secretary, (1) reinvested in another project at the airport, or (2) transferred to another eligible airport as prescribed by the Secretary. The Secretary shall give preference to the following, in descending order, (1) reinvestment in an approved noise compatibility project, (2) reinvestment in an approved project that is eligible for grant funding under Section 47117(e) of title 49 United States Code, (3) reinvestment in an approved airport development project that is eligible for grant funding under Sections 47114, 47115, or 47117 of title 49 United States Code, (4) transferred to an eligible sponsor of another public airport to be reinvested in an approved noise compatibility project at that airport, and (5) paid to the Secretary for deposit in the Airport and Airway Trust Fund. If land acquired under a grant for noise compatibility purposes is leased at fair market value and consistent with noise buffering purposes, the lease will not be considered a disposal of the land. Revenues derived from such a lease may be used for an approved airport development project that would otherwise be eligible for grant funding or any permitted use of airport revenue.

b. For land purchased under a grant for airport development purposes (other than noise compatibility), it will, when the land is no longer needed for airport purposes, dispose of such land at fair market value or make available to the Secretary an amount equal to the United States' proportionate share of the fair market value of the land. That portion of the proceeds of such disposition which is proportionate to the United States' share of the cost of acquisition of such land will, (1) upon application to the Secretary, be reinvested or transferred to another eligible airport as prescribed by the Secretary. The Secretary shall give preference to the following, in descending order: (1) reinvestment in an approved noise compatibility project, (2) reinvestment in an approved project that is eligible for grant funding under Section 47117(e) of title 49 United States Code, (3) reinvestment in an approved airport development project that is eligible for grant funding under Sections 47114, 47115, or 47117 of title 49 United States Code, (4) transferred to an eligible sponsor of another public airport to be reinvested in an approved noise compatibility project at that airport, and (5) paid to the Secretary for deposit in the Airport and Airway Trust Fund.

c. Land shall be considered to be needed for airport purposes under this assurance if (1) it may be needed for aeronautical purposes (including runway protection zones) or serve as noise buffer land, and (2) the revenue from interim uses of such land contributes to the financial self-sufficiency of the airport. Further, land purchased with a grant received by an airport operator or owner before December 31, 1987, will be considered to be needed for airport purposes if the Secretary or Federal agency making such grant before December 31, 1987, was notified by the operator or owner of the uses of such land, did not object to such use, and the land continues to be used for that purpose, such use having commenced no later than December 15, 1989.

d. Disposition of such land under (a) (b) or (c) will be subject to the retention or reservation of any interest or right therein necessary to ensure that such land will only be used for purposes which are compatible with noise levels associated with operation of the airport.

32. **Engineering and Design Services.** It will award each contract, or sub-contract for program management, construction management, planning studies, feasibility studies, architectural services, preliminary engineering, design, engineering, surveying, mapping or related services with respect to the project in the same manner as a contract for architectural and engineering services is negotiated under Title IX of the Federal Property and Administrative Services Act of 1949 or an equivalent qualifications-based requirement **prescribed** for or by the sponsor of the airport.

33. **Foreign Market Restrictions.** It will not allow funds provided under this grant to be used to fund any project which uses any product or service of a foreign country during the period in which such foreign country is listed by the United States Trade Representative as denying fair and equitable market opportunities for products and suppliers of the United States in procurement and construction.

34. **Policies, Standards, and Specifications.** It will carry out the project in accordance with policies, standards, and specifications approved by the Secretary including but not limited to the advisory circulars listed in the Current FAA Advisory Circulars for AIP projects, dated ____________________ (the latest approved version as of this grant offer) and included in this grant, and in accordance with applicable state policies, standards, and specifications approved by the Secretary.

35. **Relocation and Real Property Acquisition.** (1) It will be guided in acquiring real property, to the greatest extent practicable under State law, by the land acquisition policies in Subpart B of 49 CFR Part 24 and will pay or reimburse property owners for necessary expenses as specified in Subpart B. (2) It will provide a relocation assistance program offering the services described in Subpart C and fair and reasonable relocation payments and assistance to displaced persons as required in Subpart D and E of 49 CFR Part 24. (3) It will make available within a reasonable period of time prior to displacement, comparable replacement dwellings to displaced persons in accordance with Subpart E of 49 CFR Part 24.

36. **Access By Intercity Buses**. The airport owner or operator will permit, to the maximum extent practicable, intercity buses or other modes of transportation to have access to the airport; however, it has no obligation to fund special facilities for intercity buses or for other modes of transportation.

37. **Disadvantaged Business Enterprises.** The recipient shall not discriminate on the basis of race, color, national origin or sex in the award and performance of any DOT-assisted contract or in the administration of its DBE program or the requirements of 49 CFR Part 26. The Recipient shall take all necessary and reasonable steps under 49 CFR Part 26 to ensure non discrimination in the award and administration of DOT-assisted contracts. The recipient's DBE program, as required by 49 CFR Part 26, and as approved by DOT, is incorporated by reference in this agreement. Implementation of this program is a legal obligation and failure to carry out its terms shall be treated as a violation of this agreement. Upon notification to the recipient of its failure to carry out its approved program, the Department may impose sanctions as provided for under Part 26 and may, in appropriate cases, refer the matter for enforcement under 18 U.S.C. 1001 and/or the Program Fraud Civil Remedies Act of 1986 (31 U.S.C. 3801).

38. **Hangar Construction.** If the airport owner or operator and a person who owns an aircraft agree that a hangar is to be constructed at the airport for the aircraft at the aircraft owner's expense, the airport owner or operator will grant to the aircraft owner for the hangar a long term lease that is subject to such terms and conditions on the hangar as the airport owner or operator may impose.

39. **Competitive Access.**

    a. If the airport owner or operator of a medium or large hub airport (as defined in section 47102 of title 49, U.S.C.) has been unable to accommodate one or more requests by an air carrier for access to gates or other facilities at that airport in order to allow the air carrier to provide service to the airport or to expand service at the airport, the airport owner or operator shall transmit a report to the Secretary that-

        1) Describes the requests;
        2) Provides an explanation as to why the requests could not be accommodated; and
        3) Provides a time frame within which, if any, the airport will be able to accommodate the requests.

    b. Such report shall be due on either February 1 or August 1 of each year if the airport has been unable to accommodate the request(s) in the six month period prior to the applicable due date.

Narrative

Brief narrative statement of facts, conditions and circumstances pertinent to the accident/incident:

*** Note: NTSB investigators may have traveled in support of this investigation and used data provided by various sources to prepare this aircraft accident report. ***

On June 21, 2001, at 1405 eastern daylight time, an amateur-built Masko Mustang MII, N24898, piloted by a commercial pilot, was destroyed when it impacted terrain following a loss of control while maneuvering in the traffic pattern at the Ann Arbor Municipal Airport (ARB), Ann Arbor, Michigan. The aircraft had just completed a touch and go and was turning from the upwind to the crosswind leg of the traffic pattern for runway 06 (3,500 feet by 75 feet, concrete). The local flight was being operated under the provisions of 14 CFR Part 91 and was not on a flight plan. Visual meteorological conditions prevailed at the time of the accident. The pilot and the pilot rated passenger received fatal injuries. The flight originated from ARB at 1353.

Witnesses to the accident saw the airplane make a steep right turn prior to spiraling to the ground.

A postaccident examination of the airplane revealed no anomalies that could be associated with a pre-impact condition.

The pilot held commercial and certified flight instructor certificates with airplane single engine land and instrument airplane ratings. The pilot also held a ground instructor certificate with advanced and instrument ratings. According to Federal Aviation Administration records, the pilot reported having 398 hours of flight time as of March 15, 2001. The pilot's logbook was not recovered.

The pilot rated passenger held a commercial pilot certificate with airplane single engine land and instrument airplane ratings. He held a certified flight instructor certificate with an airplane single engine land rating. The pilot rated passenger also held a ground instructor certificate with an advanced rating. According to Federal Aviation Administration records, the pilot rated passenger reported having 307 hours of flight time as of May 10, 2001. The pilot rated passenger's logbook was not recovered.

Toxicology tests performed on the pilot and pilot rated passenger were negative for all tests performed. Autopsies were performed on the pilot and pilot rated passenger by Washtenaw County on June 22, 2001.

It was reported that the airplane was purchased on June 16, 2001. The pilot was the flight instructor of the new owner. The owner was not aboard the airplane when the accident occurred.

Narrative

Brief narrative statement of facts, conditions and circumstances pertinent to the accident/incident:

*** Note: NTSB investigators either traveled in support of this investigation or conducted a significant amount of investigative work without any travel, and used data obtained from various sources to prepare this aircraft accident report. ***

HISTORY OF FLIGHT

On December 1, 1994, about 1007 central standard time, an Agusta SPA A109A II, N1QF, operated by Metro Aviation, Inc., was destroyed when it collided with the terrain near Ann Arbor, Michigan. The commercial pilot and two passengers (medical evacuation crew members) were fatally injured. The 14 CFR Part 91 positioning flight departed the St. Joseph Hospital in visual meteorological conditions about 1003, en route to Howell, Michigan. The purpose of the flight was to pick up a patient at Howell, and return to St. Joseph's Hospital.

Prior to the morning of the accident N1QF was designated as the standby helicopter; however, the primary helicopter was scheduled for maintenance on the day of the accident, therefore essential equipment had to be moved from the primary craft to N1QF. Before the transfer could be accomplished, N1QF was required to prepare for dispatch on the accident flight. What was later described by a witness as a "hasty dispatch," necessitated a hurried departure to accomplish the transfer of equipment, complete a preflight,and other items necessary for a medical evacuation flight. The witness to the departure stated that a complete preflight was accomplished by the crew; although this witness did not actually have an opportunity to watch the entire preparation. The witness indicated that the start of the engines was "normal," with no delay in the engine start up. The flight departed at 1003.

At 1005 N1QF contacted the Ann Arbor, Federal Aviation Administration (FAA) Control Tower (ATCT), giving its position as one and one half miles east of St. Joseph's Hospital and requesting landing permission stating, in part, "I'd like to proceed inbound.. single engine landing, please." Six seconds later the flight was cleared into the class D surface area. Seven seconds later, N1QF responded stating, "Ah, disregard, I'm going down at this time." No additional information was transmitted, nor was the reason for the single engine landing stated. The pilot did not declare an emergency nor did he request assistance.

The pilot then contacted the dispatcher, at St. Joseph's Hospital and stated that he was going to land, "north of the university." The dispatcher requested the information be repeated and the pilot did so. There was no indication of any need for assistance, the nature of any emergency situation, nor was there any discussion of difficulties being experienced by the flight. Twenty-six seconds after the pilot's repeating the location to the dispatcher, he made a final transmission, indicating a crash was imminent.

Eyewitnesses observed the accident helicopter during the final few seconds of the flight. Two

Narrative (Continued)

witnesses stated that the helicopter was trailing smoke from the area of the engines. One witness indicted that the helicopter was maneuvering just prior to the impact and that during the final descent which he described as "dropped like a stone," it appeared the rotor blades were "not turning hardly at all." Witnesses reported that the helicopter was nearly silent just prior to ground impact and that there was no engine noise at all after impact.

OTHER DAMAGE

One small tree was damaged during the impact with the terrain.

PERSONAL INFORMATION

The pilot was born May 27, 1952, and was the holder of a commercial helicopter certificate number 2157108, with instrument helicopter privileges. At the time of the accident he had 5,000 hours flight time, with 3,500 hours of pilot in command time and 300 hours in the make and model of helicopter involved in the accident. He held a second class medical certificate issued June 9, 1994. His most recent biennial flight review was accomplished in an Agusta A109 on October 23, 1994.

AIRCRAFT INFORMATION

The helicopter was an Agusta SPA A109A II, serial number 7311, N1QF. The helicopter was maintained on an Approved Inspection Program. The most recent inspection occurred on June 13, 1994, with a total time in service of 1,870 hours. The helicopter had accumulated 57 hours since the inspection, at the time of the accident. The helicopter was last fueled on November 22, 1994.

WRECKAGE AND IMPACT INFORMATION

The helicopter impacted flat terrain in a commercial area, on a northeast heading. Ground scars and eyewitness reports indicated that the helicopter impacted in a near vertical direction with little forward motion. The landing gear was found in the extended (gear down) position. The helicopter was lying on its left side. The fuselage was crushed to about one-half the original height. The tail boom was partially separated from the fuselage from ground impact and impact with a small tree. Three of the main rotor blades were intact with little bending. The tail rotor assembly had impact damage only with no rotational damage evident. The main rotor head exhibited marks and damage consistent with blade coning impact.

The rotor system was inspected during the on scene phase of the investigation including the main and tail rotors, transmission and gearbox. No discrepancies were noted.

Both engines and the transmission exhibited little impact damage and were removed for further study. During the on-scene investigation both engines rotated and there was continuity throughout the gear train. No damage was visible in the output drive shafts on either engine. The fuel control pointer on the number 1 engine was at 30 degrees with the throttle handle at idle. The fuel control pointer on the number 2 engine was at 85 degrees with the throttle handle about mid-range. Fuel vacuum checks were done with engine number 1 having no leaks and engine number 2 having a leak traced to the fuel pump assembly.

MEDICAL AND PATHOLOGICAL INFORMATION

A post mortem examination of the pilot was conducted by the Washtenaw County (Michigan) Medical Examiner, on December 2, 1994. No contributing pre-existing pathology was found.

A toxicological examination of specimens from the pilot proved negative for those drugs screen.

Narrative (Continued)

TESTS AND RESEARCH

Fuel samples from the fueling source were found to be free of water and within limits for Jet-A1.

Fuel and oil samples from the helicopter were tested at the Allison lab and were found to be within limits for Jet-A1 fuel and MIL-L-23699E oil.

An examination of light bulb filaments revealed stretched filaments in the "Master Warning," "Master Caution," "Engine #1 Low RPM," "Engine #2 Low RPM." and "Low Rotor RPM" panels.

Both engines were test run at Allison on a production test stand on January 11, 1995. Number 1 engine was found to be within limits. Number 2 engine experienced excessive compressor vibration, therefore, the control components from that engine were tested on the number 1 engine which had been successfully run. The engine operation did not reach the limits falling about 2% below top limits.

The compressor for engine number 2 was disassembled and inspected. A visual inspection revealed unusual balance marks. The rotor was check balanced and it measured at 0.006 oz-in of unbalance. The limit should have been 0.001 oz-in. Although the exact mode of unbalance was not determined, experienced sources indicated that the unusual marks could not be associated with normal operation of the engine; however could be associated with impact artifact.

The individual components (originally) from engine number 2 were tested on October 11, 1995, and the fuel control was found to fall about 2% below the top limit. There was nothing found that would have prevented the engine from operating normally at the cruise setting.

Throughout the on-scene investigation and during the testing of components, nothing was found to indicate any reason that an engine should stop running inflight. Nothing was found in either engine to indicate an indication necessitating a need to manually shut down an engine inflight.

ADDITIONAL DATA/INFORMATION

Parties to the investigation were the FAA Flight Standards District Office, Belleville, Michigan; Agusta Aerospace Corporation, Philadelphia, Pennsylvania; Allison, Indianapolis, Indiana; Allied Signal Aerospace, South Bend, Indiana; and Metro Aviation Inc., Shreveport, Louisiana.

The helicopter wreckage was released to representatives of the owner on December 16, and December 22, 1994 and January 9, 1996.

Environmental Assessment
for
Ann Arbor Municipal Airport
Ann Arbor, Michigan

Prepared for:

Michigan Department of Transportation
Bureau of Aeronautics and Freight Services
and
City of Ann Arbor

Prepared by:

JJR, LLC

This environmental assessment becomes a State of Michigan document when evaluated and signed by the responsible state official.

Responsible State Official	Date of Approval
Responsible Federal Official	Date of Approval

This Environmental Assessment describes the social, economic, and environmental impacts associated with the Preferred Alternative for implementing proposed improvements at the Ann Arbor Municipal Airport. The alternatives considered were: (1) No Build, (2) Use other airports, (3) Construct new airport, (4) Develop alternative modes of transportation, and (5) Runway 6/24 alternatives.

Comments on this Environmental Assessment should be received within 30 days of the date of publication and should be sent to Ms. Molly Lamrouex, Airports Division, MDOT Bureau of Aeronautics and Freight Services, 2700 Port Lansing Road, Lansing, Michigan 48906-2160.

ANN ARBOR MUNICIPAL AIRPORT
ENVIRONMENTAL ASSESSMENT

Appendices

Section 1.
Executive Summary

The Ann Arbor Municipal Airport (ARB), owned and operated by the City of Ann Arbor, is located in Pittsfield Township, Washtenaw County, Michigan. ARB initiated preparation of an Environmental Assessment (EA) in 2009 to evaluate the potential impacts of implementing portions of proposed developments shown on the Federal Aviation Administration (FAA) approved Airport Layout Plan (ALP).

The proposed developments focus on extending and improving Runway 6/24, the primary runway, to address the needs of the existing critical aircraft that use the airport. Alternatives were developed to provide options for extending the existing 3,505-foot runway to 4,300-feet, while extending the existing parallel taxiway to the same length. Alternatives considered in this study included no build, use other airports, construct new airport, develop alternative modes of transportation, and Runway 6/24 alternatives.

The alternatives were evaluated based on their ability to meet the purpose and need of the project, the impact the alternative would have on the community and environment, and other limiting factors, such as cost. Based on this evaluation, a build alternative that involves shifting and extending the existing runway was selected as the Preferred Alternative.

Implementation of the Preferred Alternative would not require the acquisition of land, and no homes or businesses would be displaced. The Preferred Alternative would not impact wetlands, county drains, or floodplains. The proposed project would have a positive impact on interstate commerce to the immediate Ann Arbor area, as well as enhance the safety of airport operations.

Section 2.
Purpose and Need

2.1 PROJECT LOCATION AND DESCRIPTION

Note: The following information contains a large number of aviation-related acronyms. A glossary with definitions is included in Section 10 of this document.

Ann Arbor Municipal Airport (ARB) is a public-use, general aviation airport located in Washtenaw County, Michigan. The airport is located in Pittsfield Township and consists of approximately 837 acres. ARB is generally bound by Ellsworth Road to the north, State Road to the east, and Lohr Road to the west (Figure 2-1).

ARB is in close proximity to state highways including US-23, M-14, US-12, and I-94. Direct access to the airport is from Ellsworth and State Roads. The closest public-use airport is Willow Run Airport in Ypsilanti, which is approximately 12 miles to the east (approximately a 20 minute drive by automobile). The southeastern region of Michigan has a high level of commerce, and high levels of commercial, corporate, and general aviation air traffic.

The City of Ann Arbor owns and operates ARB. The city is responsible for contracting with the Fixed Base Operators (FBO), which are Solo Aviation, Ann Arbor Aviation Center, and Bijan Air. ARB's operating budget is an enterprise fund comprised solely of revenue generated by airport operations.

The primary runway, Runway 6/24, is 3,505-feet long by 75-feet wide and is oriented in a northeast/southwest direction. ARB has 22 permanent aviation service buildings, including the administration building, the FBOs, maintenance facilities, conventional box hangars, a privately owned hangar, and the FAA Air Traffic Control Tower (ATCT). The airport also provides 150 T-hangar spaces in an additional 13 T-hangar structures.

The current FAA-approved Airport Layout Plan (ALP) was updated in 2008 (Figure 2-2), and it incorporates the future development proposed in the Airport Capital Improvement Plan for ARB.

The proposed improvements from the ALP that are documented in this EA include:

- Shift and extend existing Runway 6/24, resulting in a runway that would be 4,300-feet long by 75-feet wide.
- Shift and extend the parallel taxiway to coincide with the revised Runway 6/24.
- Provide a new taxiway connector to the extended Runway 6 end.
- Provide a new taxiway connector and holding bay to the shifted Runway 24 end.

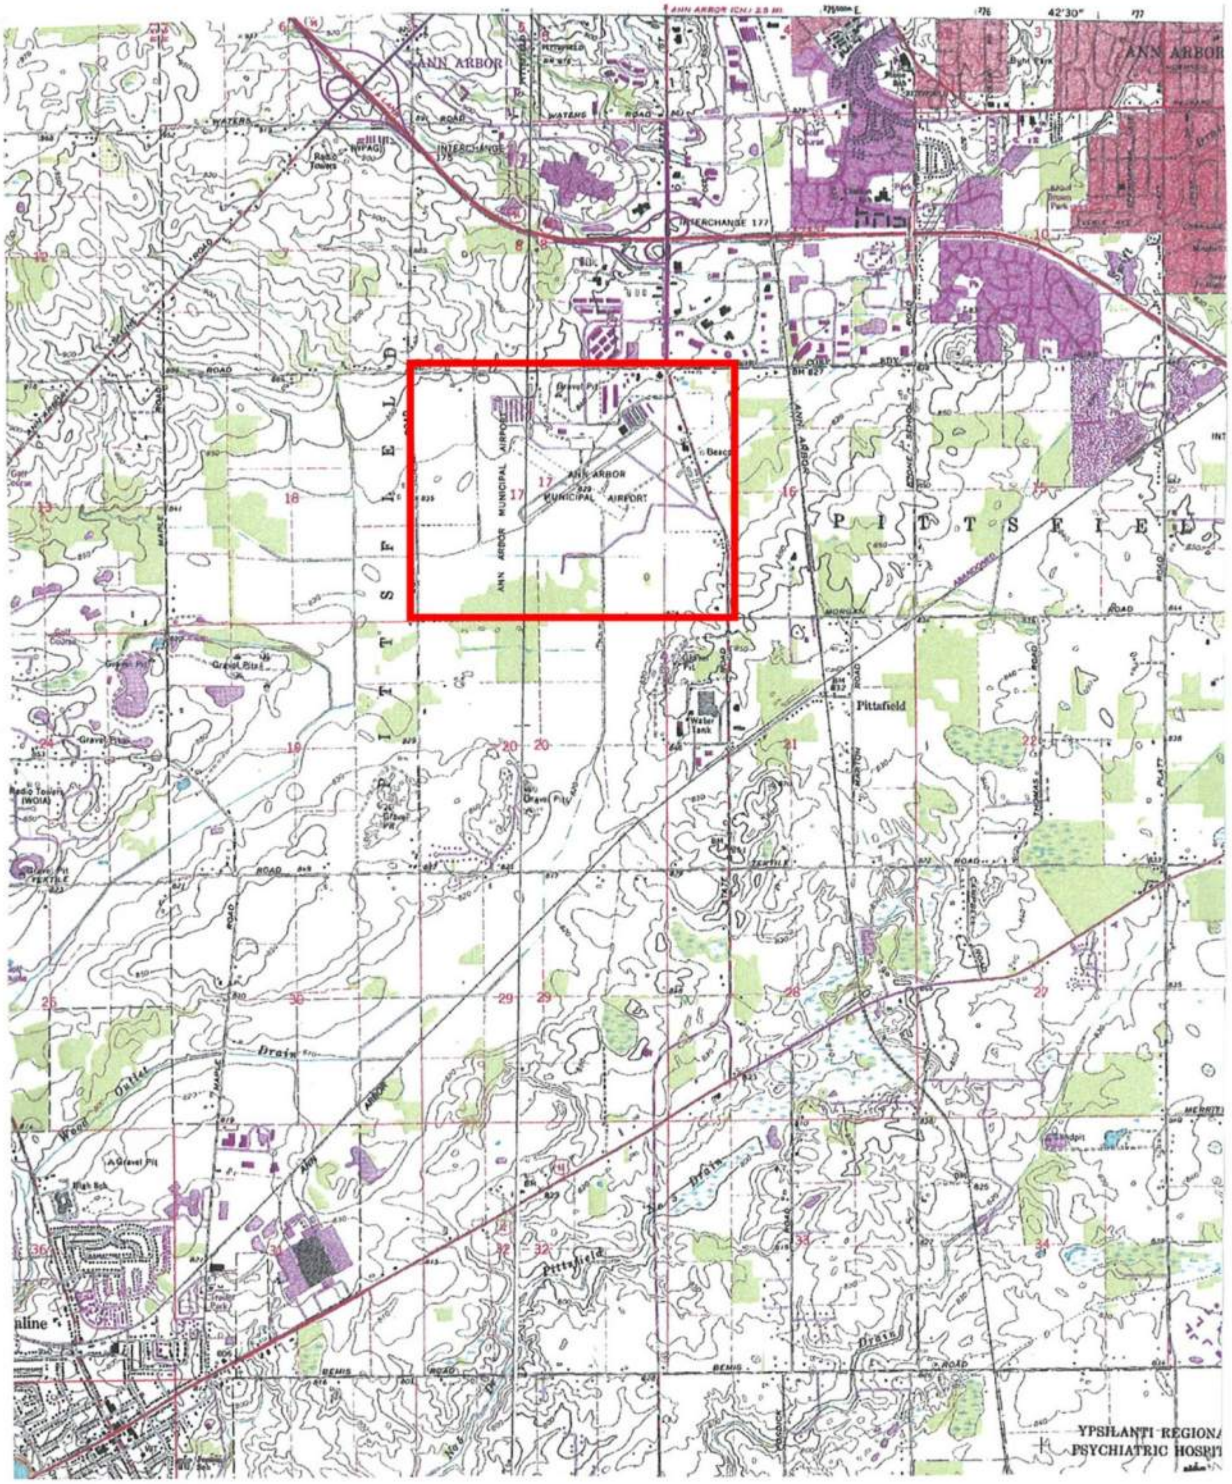

Figure 2.1: Location Map
Ann Arbor Municipal Airport Environmental Assessment

JJR

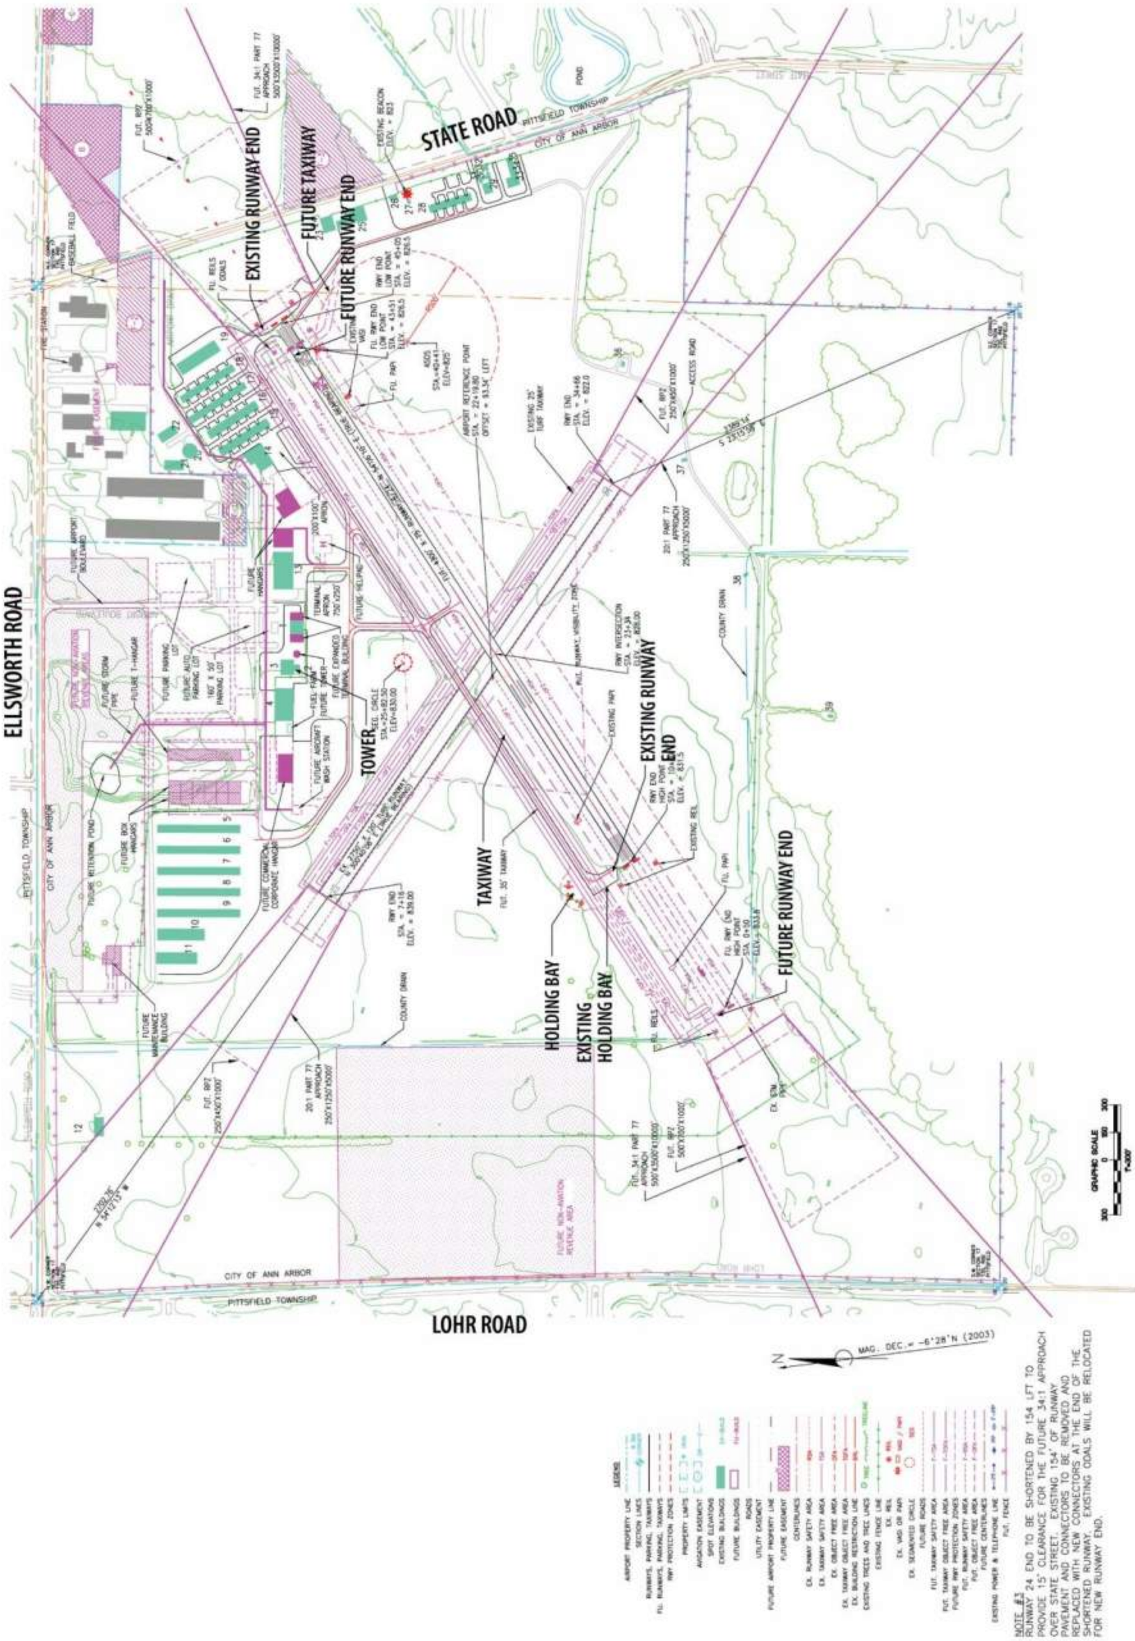

Figure 2.2: Airport Layout Plan
Ann Arbor Municipal Airport Environmental Assessment

2.2 PURPOSE AND NEED

The purpose of the proposed improvements at ARB is to provide facilities that more effectively and efficiently accommodate the *critical aircraft* that presently use the airport, as well as to enhance the operational safety of the airport.

The critical aircraft is defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the critical aircraft weigh less than 60,000 lbs, a classification of aircraft is used rather than a specific individual aircraft model.

A recent Airport User Survey has confirmed that the critical aircraft classification for ARB is “B-II Small Aircraft” (MDOT, 2009). Aircrafts in this category have runway approach speeds between 91 and 120 knots, wingspans between 49- and 79-feet, and maximum certificated takeoff weights of 12,500 lbs or less. A representative aircraft of this classification is the Beechcraft King Air 200, a twin-engine turboprop aircraft that typically seats 10-12 people, including the flight crew.

As stated in FAA Advisory Circular 150/5325-4B, “*The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions*.” Airplanes that are classified within an airport’s critical aircraft classification are considered by the FAA to be the regular use aircrafts of the primary runway.

Development of the primary runway at ARB to the recommended length of 4,300-feet would allow the majority of B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions). Interstate commerce into and out of a community can be negatively impacted if business aircraft are forced to operate with load restrictions (i.e. reductions in passengers, cargo, and fuel associated with aircraft range) due to lack of suitable runway length.

An origin-destination analysis was conducted on Instrument Flight Rules (IFR) flight plan records associated with ARB as part of the user survey process. Although the data analyzed did not include records of all operations conducted at ARB, it did confirm that there are a significant number of operations between ARB and distant locations throughout the country.

Flight operations were verified between ARB and at least 31 other states (approximately 63 percent of the continental US). Also, approximately 67 percent of the IFR flight plan records examined were between ARB and out-of-state locations. These factors are strong indicators of corporate flight activity associated with interstate commerce, as opposed to local pleasure flying by general aviation pilots. The large number of states that were linked to ARB is also a strong indicator of use of the airport by many corporations, as opposed to a single or few corporate users. Some of the larger corporations that were confirmed by the user survey as being users of ARB are Synergy International, Wells Fargo, Polaris Industries, Bombardier Aerospace, Avis Industrial Corporation, Thumb

Energy, NetJets, and AvFuel. NetJets provides on-demand air charter service and corporate aircraft fractional ownership opportunities to a large number of businesses located throughout the country. AvFuel Corporation, a nationwide supplier of aviation fuels and aviation support services, is headquartered in Ann Arbor and bases their Cessna 560 Excel Jet at ARB.

The City of Ann Arbor proposes to extend the existing 3,505-foot primary runway to 4,300-feet in total length in order to more effectively accommodate the critical aircraft that currently use the airport. The runway extension would enhance interstate commerce associated with business aviation, and the other proposed modifications would enhance the operational safety of ARB.

The objectives of the proposed project are to:

- Enhance interstate commerce by providing sufficient runway length to allow the majority of critical aircraft to operate without weight restrictions.
- Enhance operational safety by improving the FAA ATCT line-of-sight issues.
- Enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24, over State Road.
- Reduce the occurrence of runway overrun incidents by small category A-I aircraft (local objective).
- Relocate and potentially upgrade the Runway 24 Approach Light System.

2.2.1 Safety Enhancement

The proposed 150-foot shift of the Runway 24 threshold to the west would enhance the safety of ground operations by taxiing aircraft. Currently, a hangar structure blocks the line-of-sight from the FAA ATCT to a portion of the parallel taxiway at the east end of the runway, including most of the taxiway hold area for departing aircrafts. While this situation is not considered hazardous, the proposed shift would enhance operational safety, and possibly prevent a runway incursion, by expanding the view of the hold area and parallel taxiway to ATCT personnel.

The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach surface to the east end of the runway (the current approach surface is the steeper 20:1). By keeping obstructions below the flatter 34:1 approach surface, an additional margin of safety is provided between approaching aircraft and any ground-based obstacles. This is particularly beneficial when aircraft are operating in low-visibility conditions. Provision of a clear 34:1 approach surface would also potentially allow visibility minimums to the Instrument Approach Procedure to Runway 24 to be lowered to 3/4 of a mile, as opposed to the current 1-mile visibility minimum. This would enhance the all-weather capability of the airport (and also interstate commerce) by allowing aircraft to continue to access the airport when weather conditions resulted in visibility dropping below the current 1-mile minimum.

Due to the proposed relocation of the Runway 24 threshold, it is also proposed that the existing runway approach light system be relocated accordingly. The airport currently uses an Omni-Directional Approach Lighting System (ODALS) to identify the approach end of Runway 24. The sequentially-flashing strobe lights assist pilots in identifying the runway threshold location and runway centerline alignment in low-visibility conditions. Since the FAA no longer installs ODALS, the current approach light system would potentially be upgraded and replaced with the newer Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF) as part of the relocation. The MALSF would serve the same function as the ODALS, and is structurally very similar.

2.2.2 Role of the Airport

ARB is a public-use facility that serves the local community by supporting economic development and public services. The following businesses and organizations are located at and operate from the airport and employ staff that supports the operations of the airport:

- Two fixed-wing FBOs;
- A helicopter FBO;
- Three national rental car agencies;
- Two flying clubs;
- Four flight schools and pilot training centers;
- FAA ATCT; and,
- Air taxi, aircraft sales, aviation insurance and aviation fueling businesses.

ARB serves the Ann Arbor medical and biomedical industries with professional air ambulance services, transporting patients, human organs, radio isotopes, and other biomedical products and services.

Community pilots and aircraft owners are members of nonprofit organizations providing “no charge” charitable gifts of flight time to citizens in need. Some of these organizations include Wings of Mercy, Angel Flight, and Dreams and Wings. Wings of Mercy has documented 292 fights into or out of ARB since 1992 including 51 flights in 2009.

ARB is included in the FAA’s National Plan of Integrated Airport Systems (NPIAS) as a general aviation airport. Not all public-use airports are included in this nationwide airport system plan. Inclusion in the NPIAS signifies that the FAA considers this airport an important part of the nation’s air transportation system, and it makes ARB eligible to receive federal grants as part of the FAA’s Airport Improvement Program.

ARB is also included in MDOT’s Michigan Airport System Plan (MASP) (MDOT, 2008). The MASP presents the results of an airport system planning process that has been aligned with the goals and objectives of MDOT’s State Long Range Plan. The MASP supports programming decisions and is useful in evaluating programming actions related to airport system and airport facility deficiencies.

As part of the MASP development, each of Michigan's public-use airports were assigned to one of three tiers based on their contribution to the state system goals. Tier 1 airports respond to essential/critical airport system goals. These airports should be developed to their full and appropriate level. Tier 2 airports complement the essential/critical airport system and/or respond to local community needs. Focus at these airports should be on maintaining infrastructure with a lesser emphasis on facility expansion. Tier 3 airports duplicate services provided by other airports and/or respond to specific needs of individuals and small business.

The MASP identifies ARB as a Tier 1 airport, with a current MASP classification of B-II. Basic standard developmental items for B-II category airports, as outlined in Table 40 of the MASP, are a paved primary runway of 4,300-feet in length by 75-feet wide, a paved parallel taxiway, appropriate runway lighting and visual aids, a runway approach protection plan, basic pilot and aircraft services, all-weather access, year-round access, and landside access. Although it is not a requirement, MDOT encourages all of Michigan's Tier 1 airport sponsors to consider development of their airports to comply with the basic development standards outlined in the MASP.

ARB currently meets all MASP basic development standards for category B-II airports, with the exception of runway length. The current primary runway is only 3,505-feet in length by 75-feet wide. An extension of the primary runway to 4,300-feet in length would result in the airport meeting all state-recommended standards for B-II category airports.

2.2.3 Aircraft Operations and Runway Length Recommendations

The Airport Reference Code (ARC) is a coding system developed by the FAA to correlate airport design criteria with the operational and physical characteristics of the airplane types that regularly use a particular airport. The critical aircraft, or grouping of aircraft, are generally the largest, most demanding types that conduct at least 500 operations per year at the airport. The ARC for each particular airport is determined based on two characteristics of the critical aircraft: the approach speed to the runway and the wingspan of the aircraft.

The first component, designated by letter A through E, is the critical aircraft's Approach Category. This is determined by the approach speed to the runway:

- Category A: Approach speed less than 91 knots.
- Category B: Approach speed 91 knots or more, but less than 121 knots.
- Category C: Approach speed 121 knots or more, but less than 141 knots.
- Category D: Approach speed 141 knots or more, but less than 166 knots.
- Category E: Approach speed 166 knots or more.

The second component, designated by Roman numeral I through VI, is the critical aircraft's Design Group. This is determined by the wingspan of the aircraft:

- Group I: Wingspan less than 49-feet.
- Group II: Wingspan 49-feet or more, but less than 79-feet.
- Group III: Wingspan 79-feet or more, but less than 118-feet.
- Group IV: Wingspan 118-feet or more, but less than 171-feet.
- Group V: Wingspan 171-feet or more, but less than 214-feet.
- Group VI: Wingspan 214-feet or more, but less than 261-feet.

The FAA has also established categories for aircraft based on their certificated Maximum Takeoff Weights (MTOW), which are determined by each specific aircraft's manufacturer. *Small Aircraft* are those with MTOWs of 12,500 lbs. or less. *Large Aircraft* are those with MTOWs greater than 12,500 lbs.

As previously mentioned, the airport user survey confirmed that the current critical aircraft category (and ARC) for ARB is "**B-II Small Aircraft**". Based on the findings of the user survey analysis, the primary runway length recommendations by MDOT and FAA are as follows:

<u>MDOT</u> – *Source: Michigan Airport System Plan (MASP 2008)* **4,300-feet**
Table 40 (*statewide standard for all ARC B-II airports*)

<u>FAA</u> – *Source: FAA Advisory Circular 150/5325-4B,* **4,200-feet***
"Runway Length Requirements for Airport Design"
Figure 2-2 (*airport-specific standard for ARB*)

** Note: The FAA runway length recommendation was obtained from Figure 2-2 in Advisory Circular 150/5325-4B. The following specifics for ARB were used in the determination:*
<u>Airport Elevation</u>: 839-feet above mean sea level
<u>Temperature</u>: 83 degrees F mean daily maximum temp, hottest month of year (July)

The FAA recommended runway length of 4,200-feet at ARB was obtained by calculation from FAA Advisory Circular 150/5325-4B, *"Runway Length Requirements for Airport Design"*, a publication that is used nationally by the agency. The resulting recommended runway lengths are airport-specific, and can vary by hundreds of-feet from site to site, depending on the specific airport elevations and mean daily maximum temperatures used in the calculations.

The MDOT recommendation of 4,300-feet is a statewide standard for all airports in the state with category B-II critical aircraft classifications. Since airport elevations and mean maximum temperatures do not vary significantly from airport to airport in Michigan, as opposed to many other states, MDOT uses a single runway length recommendation for all airports of the same critical aircraft classification.

The existing ARC shown on the current ALP for the airport is category B-II. This classification has been confirmed correct by the recent airport user survey. Even if the proposed extension to 4,300-feet is constructed, the ALP shows that the future ARC for the airport will remain category B-II.

2.2.4 Airport Operational Forecasts

Year 2007 was the onset year of planning activities associated with the potential extension of Runway 6/24, and the year in which the airport manager and FBOs were requested to collect based and itinerant aircraft operational data for the purpose of determining project justification. In order to maintain consistency, FlightAware operational records from target year 2007 were also examined during the user survey analytical process.

Actual total operations for year 2009 were recently published (January 2010) by the FAA for airports with ATCT. From the user survey operational data year 2007 through the most recent operational data year 2009, total annual operations at ARB have decreased approximately 21.8% (from 72,853 actual in 2007 to 57,004 actual in 2009). Since the operational totals were obtained from actual ATCT records, rather than estimates, they are considered very accurate.

By applying the 21.8% decrease in total annual operations at ARB from 2007 to 2009 to the user survey results, a very accurate estimate can be obtained for the current level of operations by B-II category critical aircraft. The user survey report documents a total of 750 actual annual operations by B-II category critical aircraft from survey data year 2007. A 21.8% decrease in this number is 586 - still well above the FAA's substantial use threshold of 500. Therefore, even with the current decrease in annual operations due to the economic recession, there is still justification at the present time for the runway extension.

The FAA's Terminal Area Forecast (TAF) shows year 2009 to be a low-point in total annual operations at ARB. The TAF projects total annual operations to continually increase every single year, from year 2010 through year 2030. Since the estimated 586 annual operations by B-II category aircraft in year 2009 confirm present justification for the runway extension, the continual increase in operations that are forecasted by the TAF confirm that justification for the runway extension is substantiated through year 2030.

The following actual and forecasted Total Operations at ARB, from year 2000 through year 2030, are from the FAA data sources listed below. The Estimated Category B-II Operations for each year have been calculated based on the percentage of actual B-II operations to actual total operations in survey data year 2007.

Table 2-1
Actual and Forecasted Total Operations at ARB

Year	Total Operations	Estimated Category B-II Operations
2000	104,342 *	1,074
2001	102,321 *	1,053
2002	91,414 *	941
2003	77,051 *	793
2004	65,516 *	674
2005	67,940 *	699
2006	71,785 *	739
2007	72,853 *	750***
2008	64,910 *	668
2009	57,004 *	586
2010	56,986 **	586
2011	57,514 **	592
2012	58,073 **	598
2013	58,639 **	604
2014	59,212 **	610
2015	59,791 **	616
2016	60,376 **	622
2017	60,968 **	628
2018	61,567 **	634
2019	62,173 **	640
2020	62,786 **	646
2021	63,405 **	653
2022	64,032 **	659
2023	64,666 **	666
2024	65,307 **	672
2025	65,956 **	679
2026	66,613 **	686
2027	67,277 **	693
2028	67,948 **	700
2029	68,627 **	706
2030	69,314 **	714

* = Actual Total Operations from FAA ATCT records
** = Forecasted Total Operations from FAA TAF
*** = Actual (from User Survey)

Forecasts from the MDOT MASP also project increasing total operations at ARB from years 2010 through 2030. The MDOT forecasts, which are independent of the FAA forecasts, further substantiate the mid-term and long-term FAA projections of a rebound in activity at ARB to near survey year 2007 operational levels.

AvFuel Corporation, which bases a B-II Large category Citation 560 Excel jet at ARB, has confirmed in writing that their operations at ARB increased from 211 actual operations in 2007 to 223 actual operations in 2008. Their Chief Pilot has also submitted written documentation that forecasts their future operational levels potentially increasing to 350 to 450 operations per year at ARB.

The FAA TAF forecast, MDOT MASP forecast, and AvFuel's operational forecast all provide support to the fact that survey year 2007 operational data that was analyzed in the user survey process is a very pertinent representation of estimated future operational levels at ARB.

2.2.5 Surrounding Land Uses

ARB is bordered by Ellsworth Road to the north, Lohr Road to the west, and State Road to the east. The primary runway is situated in a northeast/southwest direction. Residential, business, industrial, recreational, agricultural, and forested areas are located adjacent to the airport, and efforts were made during the analysis of alternatives to minimize impacts to these resources. Residential properties are located along Lohr Road and business properties are located along State and Ellsworth Roads. A perennial stream crosses through the airport property and flows to the south connecting to a county drain (Wood Outlet). A portion of the stream near the southwest end of the runway is enclosed in a concrete culvert.

2.2.6 Other Considerations

Aircraft performance information and runway length requirements for each airplane are contained in the individual airplane flight operating manual. As quoted from FAA Advisory Circular 150/5325-4B, Paragraph 206, "*This information is provided to assist the airplane operator in determining the runway length necessary to operate safely. Performance information from those manuals was selectively grouped and used to develop the runway length curves in Figures 2-1 and 2-2. The major parameters utilized for the development of these curves were the takeoff and landing distances for Figure 2-1 and the takeoff, landing, and accelerate-stop distances for Figure 2-2*." As stated earlier in this section, Figure 2-2 of the Advisory Circular was used to determine the FAA-recommended runway length for ARB.

The *accelerate-stop distance* concept referred to above is an important operating consideration. In this concept, the pilot not only considers the amount of runway needed for takeoff, but also the amount of runway needed to abort the takeoff while on the takeoff roll and bring the aircraft to a stop. In situations where pilots detect a problem with the aircraft while on the takeoff roll, they are forced to continue the takeoff and contend with the problem in the air if there is not enough runway remaining to bring the aircraft to a stop. By having enough remaining runway to safely abort a takeoff and stop the aircraft while still on the ground, a pilot would be able to avoid a potentially hazardous situation of taking to the air with a mechanically-deficient aircraft.

A local objective is to reduce the occurrence of runway overrun incidents. While overrun incidents are not officially recognized by the FAA or MDOT as justification for extending runways, there is merit to this local objective. The 11 overrun incident reports that were analyzed showed that most runway overruns at ARB involved small single-engine category A-I aircraft. These types of incidents often involve student pilots or low-time, relatively inexperienced pilots. There is no evidence in the incident reports that any of the aircraft which overran the end of the existing 3,505-foot runway exceeded the limits of the 300-foot long turf Runway Safety Area. Therefore, in each of these cases, the proposed 4,300-foot long runway would have provided sufficient length for the small category A-I aircraft to safely come to a stop while still on the runway pavement, without running off the runway end.

The considerations mentioned above do not imply that the existing 3,505-foot runway is unsafe in any regard. Accelerate-stop distance requirements can be accommodated on the existing runway if pilots of critical category aircraft operate at reduced load capacities. In the cases of the previous runway overrun incidents, the turf Runway Safety Areas to the existing runway performed as designed and provided a clear area for the overrunning aircraft to come to a stop. There were no reports of personal injuries, although there were reports of aircraft damage in several of the incidents.

2.2.7 Summary

The proposed shift and extension of primary Runway 6/24 at ARB would provide a runway configuration that more effectively accommodates the critical aircraft that presently use the facility. The proposed project would satisfy the FAA design objective of providing sufficient runway length to allow airplanes that regularly use it to operate without weight restrictions. The proposed project would also result in ARB achieving full compliance with all MDOT basic developmental standards outlined in the MASP 2008 for category B-II airports.

In particular, the proposed project would provide the following benefits:

- Enhance business aviation and interstate commerce by providing sufficient runway length to allow the majority of category B-II Small critical aircraft that currently use ARB to operate without load restrictions (i.e. reduction in passengers, cargo, and fuel associated with aircraft range).
- Enhance the safety of ground operations, and lessen the chances of a runway incursion, by expanding the view of the parallel taxiway and aircraft hold area to ATCT personnel.
- Improve the all-weather capability of ARB and enhance operational safety in low-visibility conditions by providing a clear 34:1 approach surface to Runway 24.
- Address the local objective of decreasing the number of runway overruns by small category A-I aircraft by providing approximately 800-feet of additional runway pavement.

Section 3.
Description of Alternatives

Alternatives have been developed to meet the goals of ARB, improve safety and efficiency, and serve current users. The existing airport facilities include the primary runway, Runway 6/24, which is 3,505-feet long and 75-feet wide, a taxiway system, FAA ATCT, and the terminal and hangar buildings. The terminal and hangar buildings are located north of the runway. The taxiway is a full parallel taxiway and there is a turf crosswind runway. See Figure 3-1 for an illustration of existing airport conditions.

The alternatives considered include: No Build (e.g., No Action), use other airports, construct new airport, and four build alternatives for Runway 6/24. The impacts of each alternative were considered along with the ability to meet the purpose and need. An analysis and illustrations of the alternatives follow, along with a summary of their associated impacts.

3.1 ALTERNATIVES CONSIDERED AND DISMISSED

During the evaluation of ARB and its future needs, several alternatives were evaluated. The following alternatives were not considered feasible and were dismissed from further study.

3.1.1 Use Other Airports

The closest public-use airport to ARB is Willow Run Airport, approximately 12 miles east, near the City of Ypsilanti. Runway lengths at Willow Run range from 5,995-feet to 7,526-feet. Surface travel time to this airport is approximately 20 minutes. Willow Run Airport is one of the largest cargo airports in the country, transferring approximately 400 million pounds of freight through the airport annually.

Other airports within 25 miles of ARB include New Hudson-Oakland Southwest Airport (approximately 21 miles north, 3,128-foot runway), Canton-Plymouth-Mettetal Airport (approximately 22 miles northeast, 2,303-foot runway), and Tecumseh-Myers-Divers Airport (approximately 23 miles southwest, 2,660-foot runway). All three of these airports have primary runways that are shorter than the existing 3,505-foot runway at ARB.

From an operational standpoint, Willow Run Airport is capable of accommodating any of the aircraft that currently fly into ARB. Although Willow Run offers longer runway lengths, and a precision Instrument Landing System (ILS) approach procedure, many corporate users still elect to fly into ARB instead of Willow Run. This demonstrates that a large number of operators of business aircraft value the close proximity of ARB to their corporate offices and business contacts over the larger facility at Willow Run. Use of ARB over Willow Run also provides increased economic benefits to the Ann Arbor-based FBOs, as well as nearby hotels, restaurants, and other businesses.

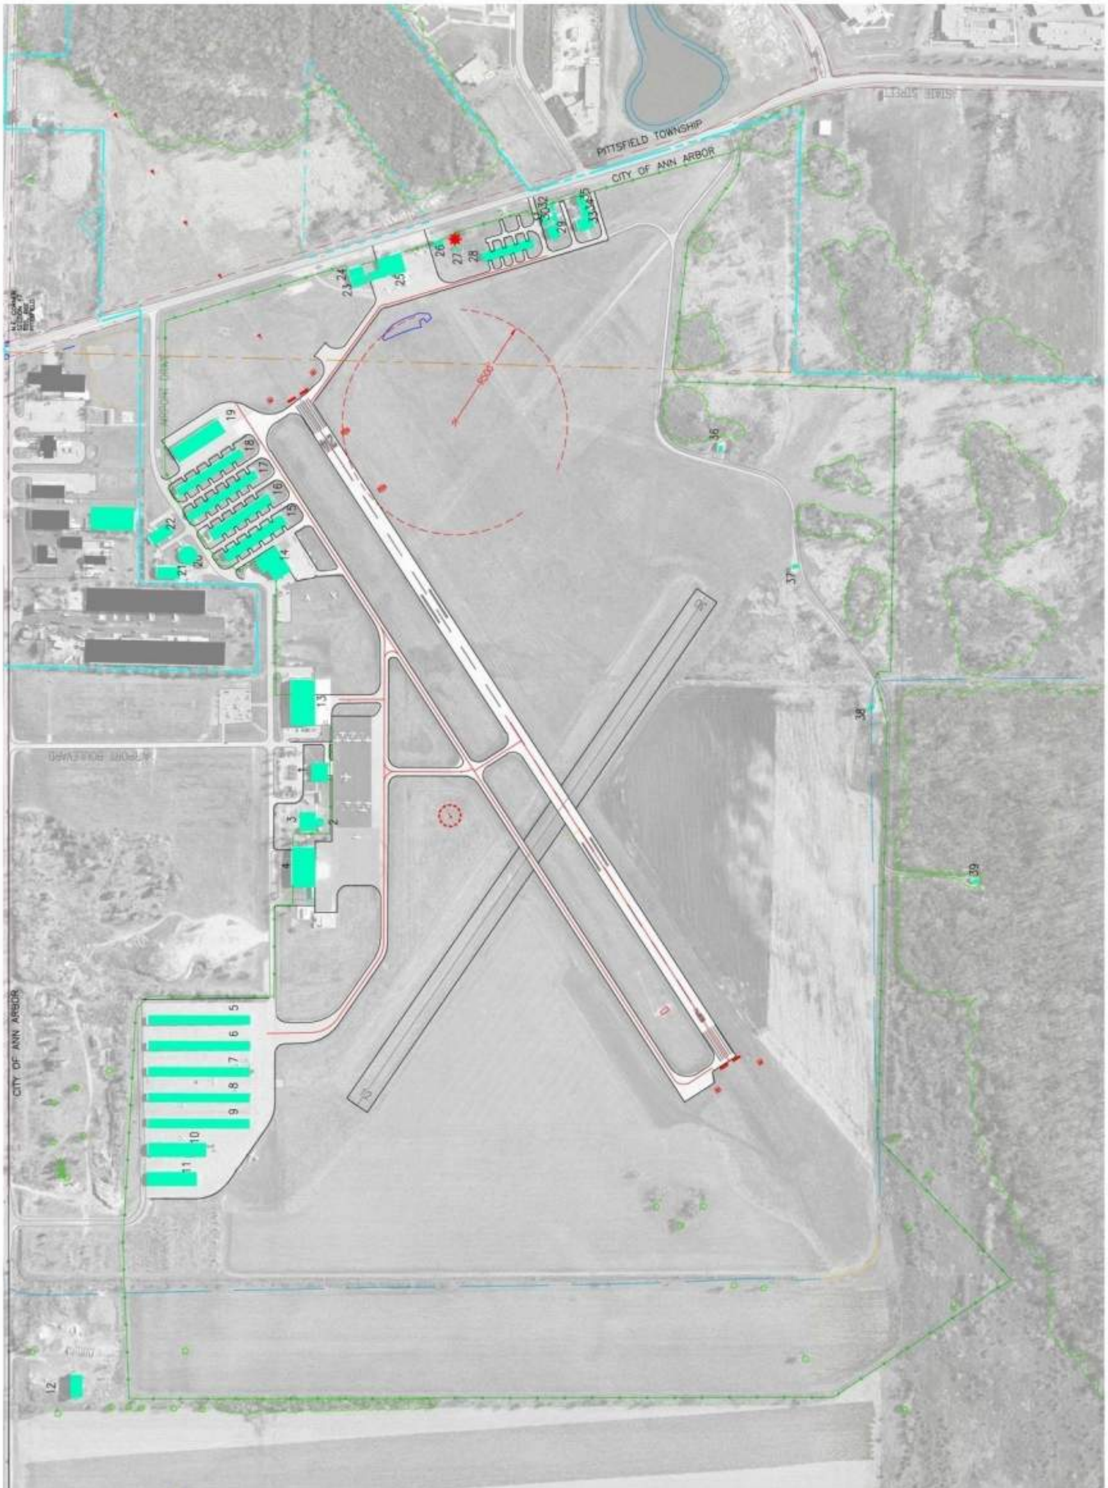

Figure 3.1: Existing Conditions
Ann Arbor Municipal Airport Environmental Assessment

Neither MDOT, nor the FAA, dictate to pilots which airports they can and cannot use. The decision on whether or not to use a particular airport is entirely up to the discretion of the pilot. Even with the availability of Willow Run, the recent airport user survey confirmed substantial use of ARB by B-II category aircrafts that are operated by many of the corporations listed in Section 2.2 of this document. The FAA design standards that are used nationally, as well as the MDOT basic development standards outlined in the MASP, are based on accommodating the existing critical aircraft that operate at each particular airport.

3.1.2 Construct New Airport

The existing airport is located in proximity to I-94, US-23, and M-14. ARB has been located at its current location since the 1920s. Many businesses have chosen their location to be in close proximity to ARB.

Relocating the operations of ARB to a new site would initially require acquisition of property comparable to, or larger than, the existing facility. While there may be sites that would physically accommodate the needs of a new airport, the costs associated with the relocation and the environmental consequences of a new airport would be greater than those expected with the expansion of ARB in its current location. It is anticipated that any site for relocation of the airport may require road closures, loss of farmlands, habitat disruption and displacement, residential relocations, and significant infrastructure improvements to provide a facility comparable to the existing airport.

It was determined that constructing a new airport would be a disruption to local businesses, considerably more expensive, and more environmentally damaging than the proposed project at the existing site. Consequently, this alternative was removed from further consideration.

3.1.3 Extend Runway to the East

This build alternative would involve extending Runway 6/24 to the east, holding the west end in its current location. The new runway would be 4,300-feet long and 75-feet wide. The parallel taxiway would also be extended to the east.

Extension of the runway pavement to the east would require the relocation of a considerable portion of State Road. Due to the FAA requirement of providing a clear Runway Safety Area, Object Free Area, and Runway Protection Zone in the approach area to the extended runway, there would also be a need to relocate a portion of Ellsworth Road, as well as the entire intersection of State Road and Ellsworth Road.

State Road and Ellsworth Road are highly traveled corridors. Any relocation would result in an impact to vehicular circulation, businesses, and residents in the area. A considerable amount of right-of-way would also have to be acquired in order to accommodate the relocated roadways, which would result in high costs and further impacts to the nearby businesses. In addition to these impacts, the relocation of State

Road would also severely impact the large wetland complex that is located on its east side.

3.2 ALTERNATIVES CARRIED FORWARD

The following alternatives were considered feasible and were carried forward for further evaluation.

3.2.1 No Build Alternative

The No Build Alternative assumes that no development would occur at ARB other than to maintain the existing facilities. The runway and taxiway would not be altered and no improvements to hangars or hangar access would occur beyond regularly scheduled maintenance.

3.2.2 Build Alternatives

When it was determined that extension of the primary runway was justified based on a determination of the airport's critical aircraft, several build alternatives were developed.

<u>Build Alternative 1 – Extend and Realign the Existing Runway</u>
The existing runway, Runway 6/24, would be realigned and extended to the southwest, holding the east end in its current location (Figure 3-2). The west end would be rotated five degrees counterclockwise. This alignment would maintain wind coverage needs, while moving the west approach away from some residential areas. The runway would be extended 800-feet to the southwest, resulting in a primary runway length of 4,300-feet with a width of 75-feet. The taxiway to the north would be extended to 4,300-feet, creating a full parallel taxiway. The taxiway and runway would have a 240-foot separation.

<u>Build Alternative 2 – Extend the Existing Runway to the West</u>
The existing runway, Runway 6/24, would be extended 800-feet to the west (Figure 3-3), holding the east end in its current location. The primary runway would be lengthened to 4,300-feet, maintaining the existing 75-foot width. As with Build Alternative 1, the existing taxiway would be extended, creating a full parallel taxiway. The taxiway and runway would have a 240-foot separation.

<u>Build Alternative 3 – Shift and Extend the Existing Runway to the West</u>
The east end of the runway would be shortened 150-feet to the west and the west end extended 950-feet to the west. The new runway would be extended a total of 800-feet, resulting in an overall runway length of 4,300-feet long and 75-feet wide (Figure 3-4). The parallel taxiway would be the same length as the runway, with a 240-foot separation.

Changes to the alignment of the primary runway are limited due to the layout of existing surface features and also by wind coverage. Desired wind coverage by FAA is 95 percent. Currently, Runways 6/24 and 13/31 provide 96.9 percent coverage with a maximum 10.5 knot cross wind component. Any change in runway alignment would need to be analyzed to determine the wind coverage.

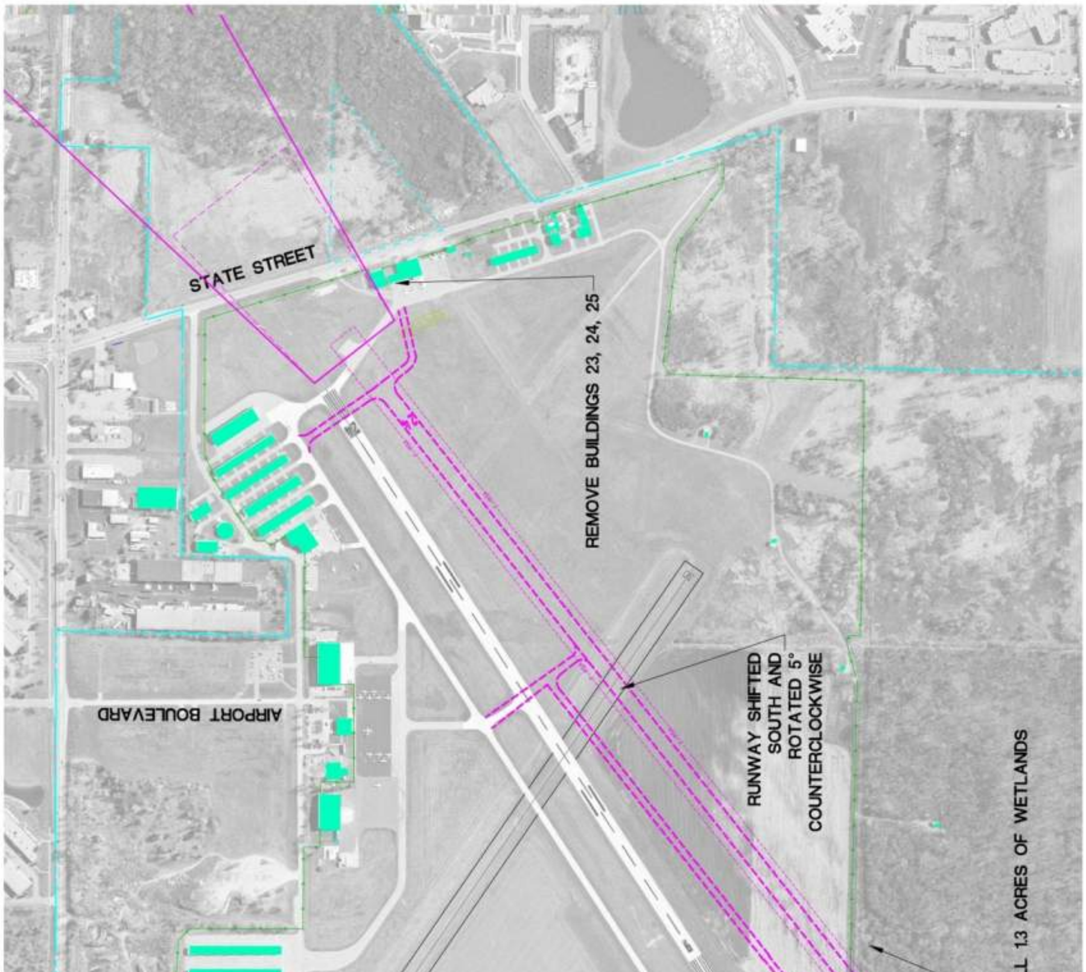

Figure 3.2: Build Alternative 1 - Extend and Realign the Existing Runway
Ann Arbor Municipal Airport Environmental Assessment

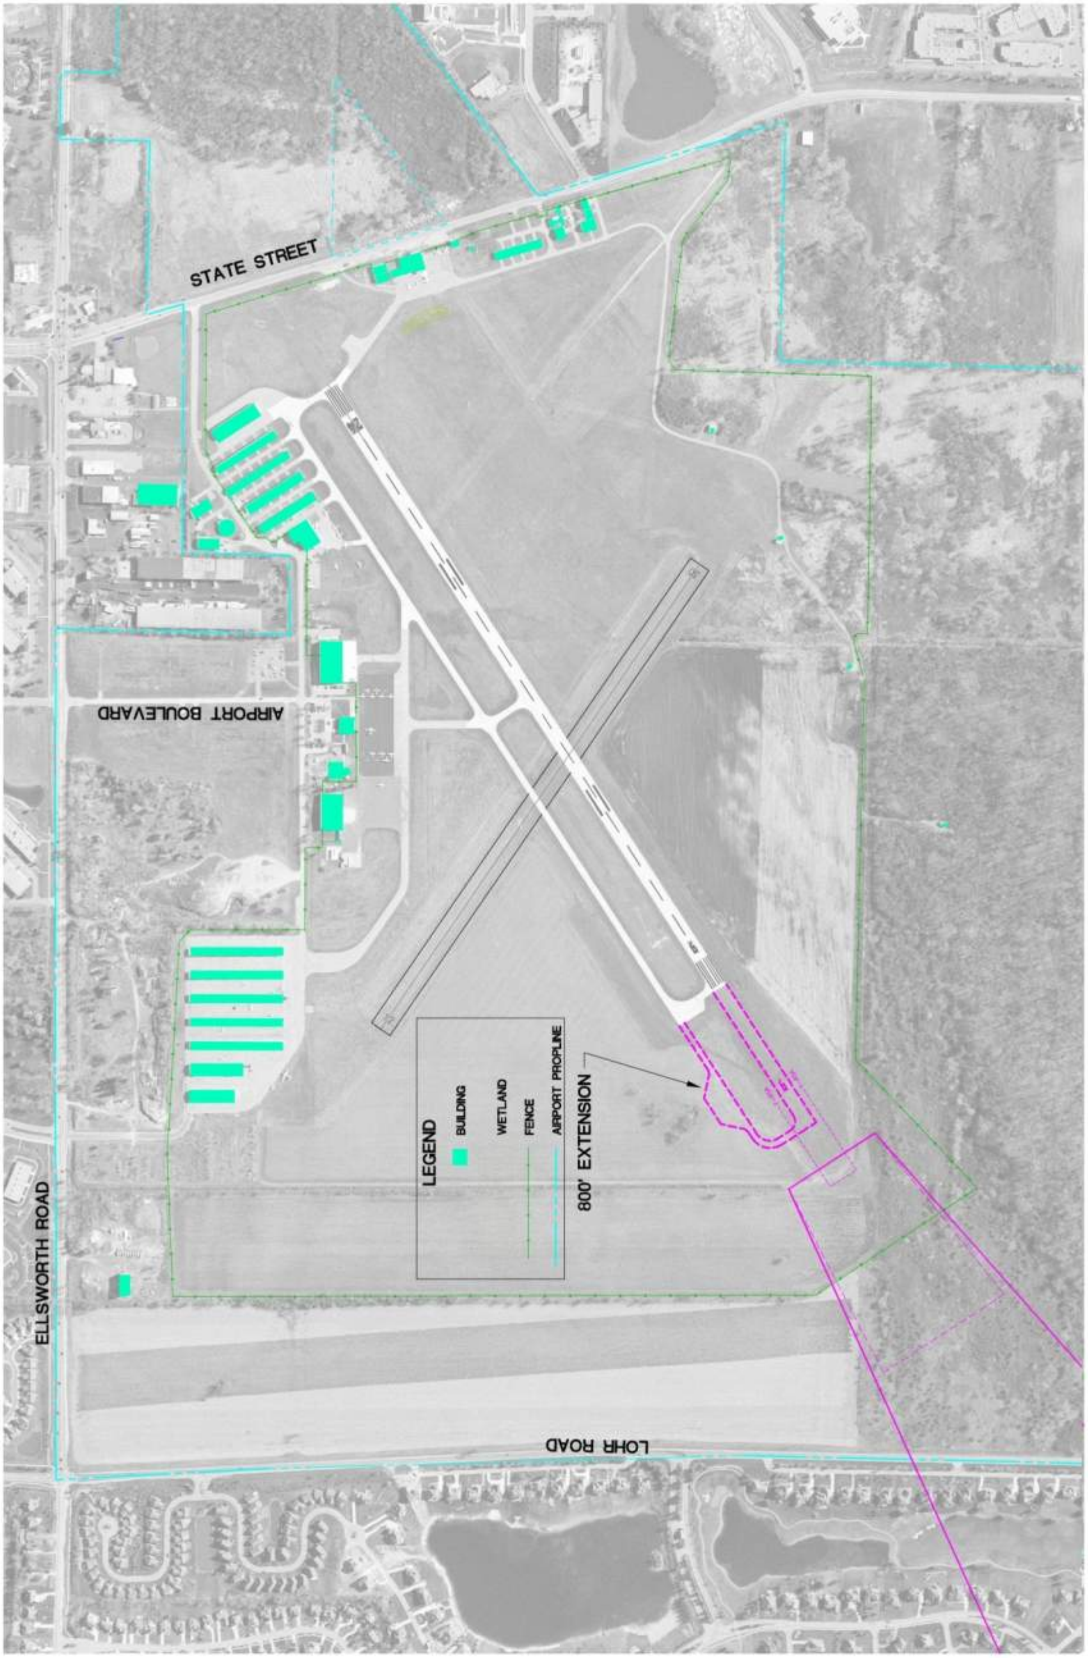

Figure 3.3: Build Alternative 2 - Extend the Existing Runway to the West
Ann Arbor Municipal Airport Environmental Assessment

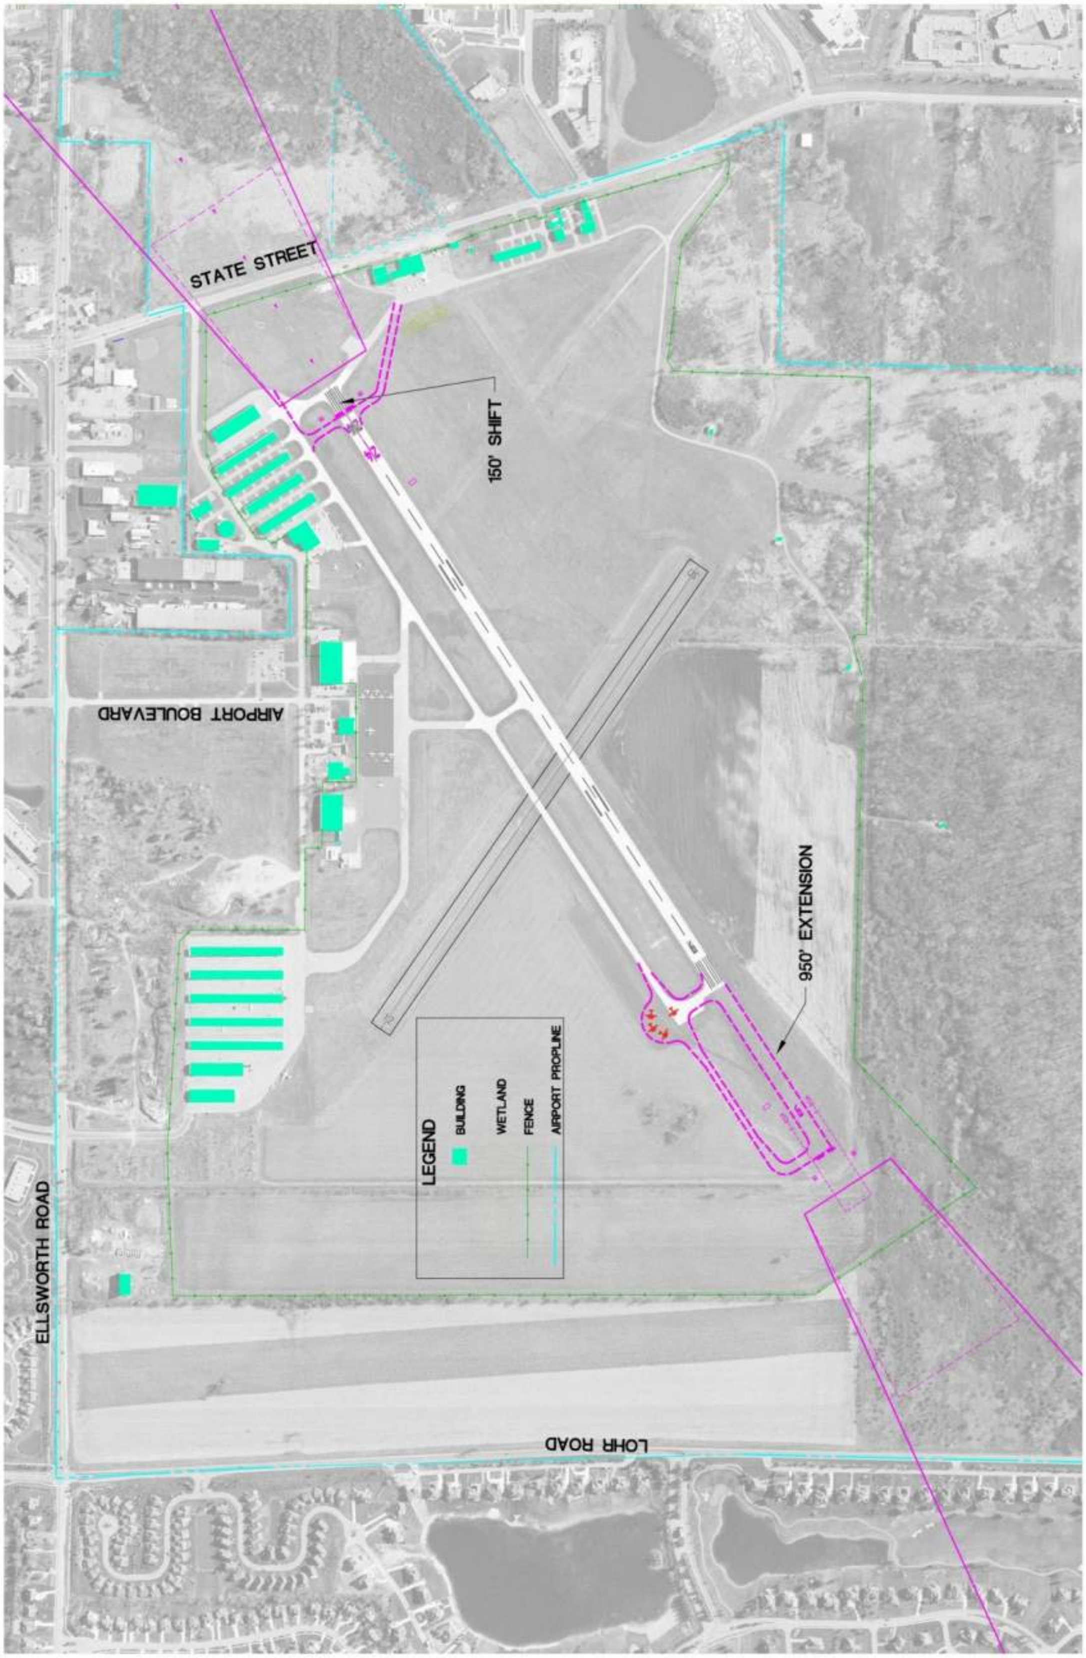

Figure 3.4: Build Alternative 3 - Shift and Extend Existing Runway to the West (Preferred Alternative)
Ann Arbor Municipal Airport Environmental Assessment

3.3 ALTERNATIVES EVALUATION

The alternatives were evaluated for: 1) ability to meet the purpose and need, and 2) extent of impacts to resources (Table 3-1). An alternative was rejected if it did not meet purpose and need, or had a high degree of impacts. The alternatives rejected and reasons for not being further considered follow.

Table 3-1
Summary of Alternatives Carried Forward

Evaluation Factors	Alternatives			
	No Build	1	2	3
Runway Length	3,500 ft.	4,300 ft.	4,300 ft.	4,300 ft.
Full Safety Areas	Yes	Yes	Yes	Yes
Stream Impact – length in feet	None	660	None	None
Direct Wetland Impacts	0 acres	1.3 acres	0 acres	0 acres
Tree clearing	0 acres	15 acres	0 acres	0 acres
Residential Displacements	0	0	0	0
Land Acquisition	0	8 acres	0	0
Airport Buildings Removed	None	3	None	None
Meets Purpose and Need	No	No	No	Yes

3.3.1 No Build Alternative

The No Build Alternative would be the least expensive alternative in the near future; however, it does not meet the objective of ARB to better serve current users, and to increase safety and efficiency. The existing runway length does not allow for the critical aircraft (B-II) to operate at their design capabilities without weight restrictions.

3.3.2 Build Alternative 1 – Extend and Realign the Existing Runway

Implementation of Build Alternative 1 would impact 1.3 acres of wetlands and extend the existing culvert of the stream by additional 660-feet. Fifteen acres of trees would need to be cleared at the west end of the new realigned runway. Three buildings at the east end of the runway would need to be removed. The property line would be 1,000-feet from the start of this approach. This would provide 50-feet of clearance at the 20:1 approach slope on this approach. Approximately 8 acres of land southwest of the runway would require an easement to clear the 20:1 approach in this area. This alternative was rejected due to the impacts to the natural resources and required land acquisition. In addition, this alternative would not allow for the future expansion of State Road, as recommended in the 2006 State Road Corridor Study.

3.3.3 Build Alternative 2 – Extend the Existing Runway to the West

Build Alternative 2 would not result in impacts to wetlands or the stream. No buildings at ARB would be removed. This alternative was rejected because it would not meet the purpose and need of the project. Keeping the east runway end in its current location would not address the tower line of sight issue or the need for a 34:1 approach on the east end. In addition, this would not allow for the future expansion of State Road, as recommended in the 2006 State Road Corridor Study.

3.3.4 Build Alternative 3 – Shift and Extend the Existing Runway to the West

Build Alternative 3 would avoid impacts to wetlands, the stream, and the buildings at ARB. This alternative would fully meet the project purpose and need. By both shifting and extending the runway, this would accommodate the existing users, improve the tower line of sight issue, and the 34:1 approach surface to Runway 24. This alternative would accommodate future widening of State Road, as recommended in the 2006 State Road Corridor Study.

3.4 PREFERRED ALTERNATIVE

Build Alternative 3 was selected as the Preferred Alternative. This alternative involves shifting and extending Runway 6/24 and the parallel taxiway (Figure 3-4). This alternative would have no significant impacts while meeting the objectives of the project's purpose and need.

This alternative would not impact wetlands or the stream. There would be no displacements, either residential or business, and no removal of buildings at ARB. A noise analysis was conducted to determine if there would be a change in the noise levels as a result of the proposed improvements. According to the noise impact analysis, the 65 Day-Night Average Sound Level (DNL) contour for the proposed runway does not extend beyond airport property and is not within 1000-feet of any residential structure. Therefore, no residents are living within areas exposed to noise levels above the 65 DNL. For more information regarding the noise analysis for this project, please refer to Section 4.1.

Of the alternatives analyzed, Build Alternative 3 is the one that best achieves the goals of the study, while providing the fewest impacts to the surrounding area. The goals include a more efficient accommodation of the critical aircraft that currently use the facility, as well as enhancement of airport operational safety. Operational safety would be enhanced by improving the line-of-sight from the FAA ATCT to the Runway 24 hold area, and by providing a clear 34:1 approach surface to the Runway 24 threshold.

Section 4.
Affected Environment and Environmental Consequences

This section describes existing conditions within ARB and the immediate surrounding areas. Potential environmental impacts associated with the Preferred Alternative are presented and described with regard to the following categories: noise analysis; compatible land use; socio-economics; air quality; historic resources; contaminated sites; and the physical and ecological environment.

There would be unavoidable short-term impacts associated with the Preferred Alternative; however, the project would have a positive impact on the operation and safety of ARB and its role in the community. The project would comply with all federal, state, and local laws and regulations.

4.1. NOISE ANALYSIS

An assessment of the project aircraft noise exposure in the areas surrounding the ARB is provided in this section. A more detailed and technical analysis is provided in Appendix B. Section 4.1.1 provides an overview of the methods used to develop noise exposure maps, and Section 4.1.2 presents the noise exposure maps, which identify the areas affected by aircraft noise.

4.1.1 Methodology

The evaluation of the ARB noise environment, and land use compatibility associated with airport noise, was conducted using the methodologies developed by the FAA and published in FAA Order 5050.4B, FAA Order 1050.1E, and title 14 Code of Federal Regulations (CFR) part 150.

For aviation noise analysis, the FAA has determined that the cumulative noise energy exposure of individuals to noise resulting from aviation activities must be established in terms of yearly DNL. DNL is a 24-hour time-weighted-average noise metric expressed in A-weighted decibels (dBA) that accounts for the noise levels of all individual aircraft events, the number of times those events occur, and the time of day which they occur. In order to represent the added intrusiveness of sounds occurring during nighttime hours (10:00 p.m. to 7:00 a.m.), DNL penalizes, or weights, events occurring during the nighttime periods by 10 dBA. This is due to the increased sensitivity to noise during normal sleeping hours and because ambient (without aircraft) sound levels during nighttime are typically about 10 dB lower than during daytime hours.

The FAA's Integrated Noise Model (INM) Version 7.0a was used to develop noise exposure contours in order to assess the noise impacts associated with the proposed extension of Runway 6/24. The INM has been FAA's standard tool since 1978 for determining the predicted noise impact in the vicinity of airports.

The INM incorporates the number of annual average daily daytime and nighttime flight and run-up operations, flight paths, run-up locations, and flight profiles of the aircraft along with its extensive internal database of aircraft noise and performance information, to calculate the DNL at many points on the ground around an airport. The noise exposure contours represent computer-generated lines connecting these points of equal noise levels resulting from aircraft operations.

The input data required in the INM to develop noise exposure contours includes:

- Aircraft operations
- Aircraft fleet
- Runway end utilization
- Ratio of daytime and nighttime aircraft operations
- Flight tracks

Aircraft operation data was collected from multiple sources, including:

- Flight Explorer®, computer software which obtains N-number (registration number), aircraft type, arrival and departure airport, and time of day from Air Traffic Control Tower radar data;
- USDOT, FAA Airport Master Record, Form 5010 July 2009;
- FAA Terminal Area Forecast (TAF) December 2008;
- FAA Air Traffic Activity Data System (ATADS) May 2009; and,
- Michigan Department of Transportation Airport User's Survey Report 2009.

INM-modeled annual operations for the 2009 existing condition, consisting of operations from April 2008 through March 2009, totaled 61,969 operations, which is approximately 169 daily operations. Jet operations accounted for approximately 2 percent of the total operations. Nighttime operations accounted for 4.2 percent of the total operations.

2014 future condition aircraft operations were obtained from the 2008 FAA TAF for ARB. Modeled annual operations for the 2014 future condition totaled 69,717 operations, or approximately 191 daily operations. The percent of night and jet operations would remain constant between the existing condition and the future years. In addition, fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives would remain static. The existing and future fleet mix with annual operations is shown in Appendix B as Table B-2.

Runway end utilization was based on discussions with the ATCT staff. Runway utilization is approximately 30 percent on Runway 6 (west end) and 70 percent on Runway 24 (east end). Discussions with ATCT staff also indicate that approximately 5 percent of single engine piston aircraft operations occur on Runway 12/30 with a 50/50 split (north end versus south end). Helicopters operate to and from the east edge of the terminal apron. Table B-3 in Appendix B provides runway utilization by aircraft category. The 2014 No-Action and Proposed Project Alternatives would maintain the same runway utilization.

Flight tracks are the aircraft's actual path through the air projected vertically onto the ground. Due to the level of operations occurring at ARB, a single arrival and departure track for each runway end was appropriate for the noise modeling. Straight out departures tracks were modeled for all runways. Straight in arrivals to Runway 12/30 were modeled and arrivals to Runway 6/24 followed the published instrument approach (Very High Frequency Omni Range (VOR)) procedures.

Unique helicopter and touch-and-go flight tracks were also modeled based on ATCT interviews. Eighty percent of the helicopter operations arrive from or depart to the north, with the remaining 20 percent distributed evenly between arrivals from and departures to the east, south, and west.

4.1.2 Aircraft Noise Exposure

The INM was used to develop 65, 70, and 75 DNL noise contours for the following scenarios:

- Existing conditions (Year 2009) – 6/24 Runway length 3,500 feet.
- No Action future conditions (Year 2014) – 6/24 Runway length 3,500 feet.
- Preferred Alternative future conditions (Year 2014) – 6/24 Runway length 4,300 feet.

DNL contours are a graphical representation of how the noise from the airport's average annual daily aircraft operations is distributed over the surrounding area. The INM can calculate sound levels at any specified point so that noise exposure at representative locations around an airport can be obtained.

The noise exposure maps developed by the INM program for the three scenarios are presented in Figure 4-1 through Figure 4-3.The noise contours (65, 70, and 75) for each scenario are super-imposed over an aerial. For the purposes of assessing the impacts related to aircraft noise, the contour maps were evaluated with respect to the number of dwelling units and number of people located within the 65 DNL contours. As stated in the FAA Order 1050.1E, Environmental Impacts: Policies and Procedures, "*A significant noise impact would occur if analysis shows that the proposed action will cause noise sensitive areas to experience an increase in noise of DNL 1.5 dB or more at or above DNL 65 dB noise exposure when compared to the no action alternative for the same timeframe*."

Existing Conditions

No homes or noise sensitive land uses are located within the 65 DNL contour for the existing conditions (Figure 4-1). The existing condition 65 DNL contour does not extend beyond airport property.

No Build Alternative (2014)

Noise exposure resulting from aircraft operations for the 2014 No Build Alternative does not impact homes or noise sensitive land uses (Figure 4-2). The 2014 No Build Alternative DNL 65 dBA noise contour does not extend beyond airport property.

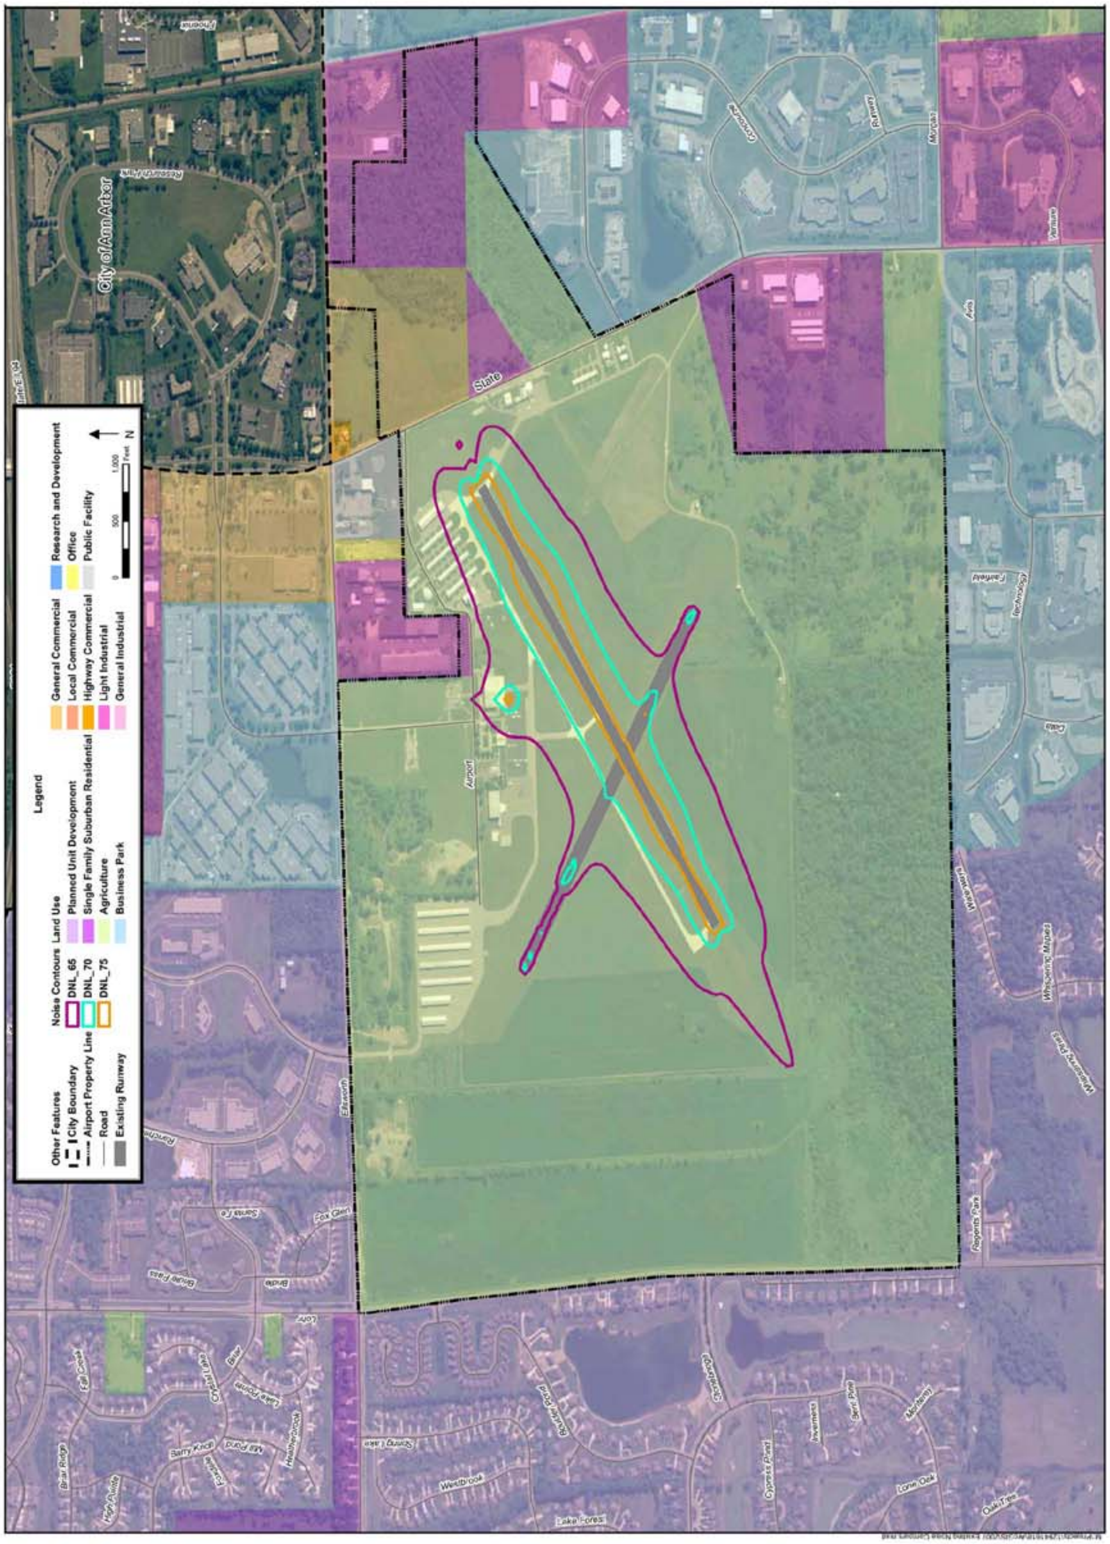

Figure 4.1: Noise Contour Map - Existing Conditions
Ann Arbor Municipal Airport Environmental Assessment

JJR

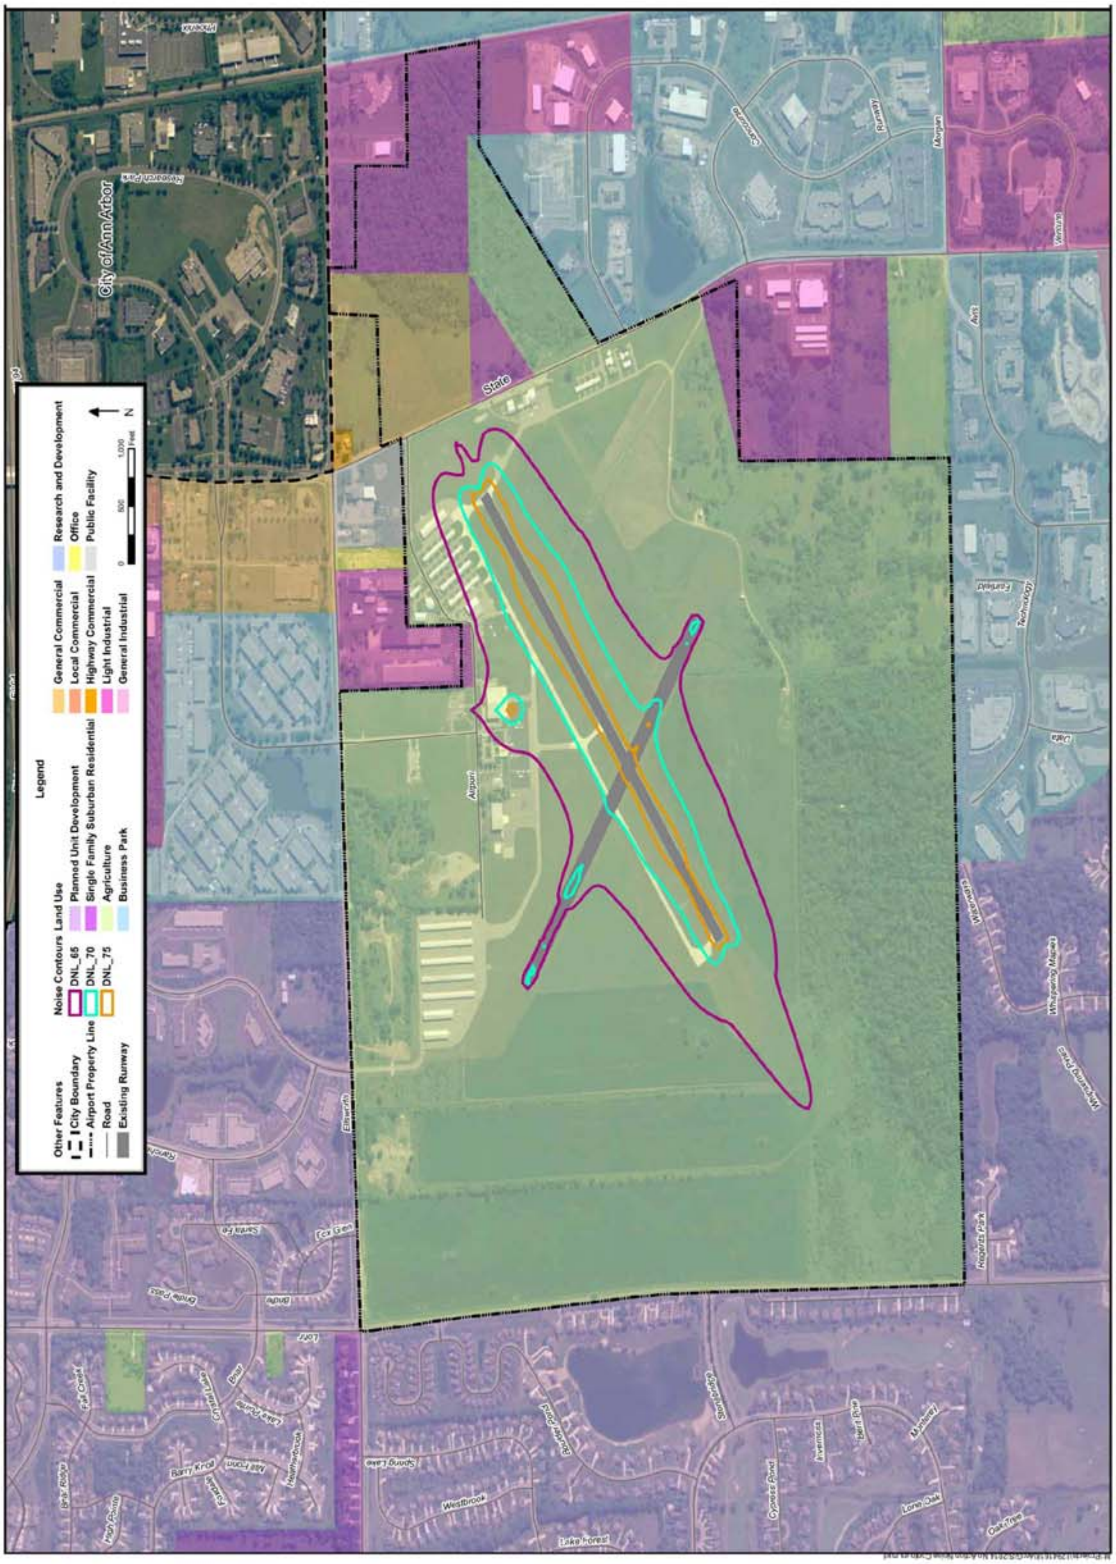

Figure 4.2: Noise Contour Map - No Build Alternative (2014)
Ann Arbor Municipal Airport Environmental Assessment

JJR

Consequences of the Preferred Alternative

No homes or noise sensitive land uses are located within the 65 DNL contour for the Preferred Alternative future conditions (Figure 4-3). This 65 DNL noise contour does not extend beyond airport property. Therefore, no people are living within areas exposed to noise levels above the 65 DNL. The Preferred Alternative is not expected to have any significant aircraft noise impacts as defined in FAA Order 5050.4B.

Proposed Mitigation Measures

The proposed Runway 6/24 extension would not result in exposure of noise levels greater than 65 DNL to residents or noise sensitive land uses. Therefore, mitigation measures are not necessary or planned in association with the proposed runway extension.

4.2 COMPATIBLE LAND USE

Existing Conditions

Land use immediately surrounding ARB includes residential, commercial, industrial, recreational, undeveloped, and agricultural areas. Access to the airport is from either Ellsworth Road to the north or State Road to the east. Along Ellsworth Road, between Lohr Road and State Road, the land use is a mix of residential (Fox Glen) and commercial, including two research and business parks (Valley Ranch, Airport Plaza). The land use along Lohr Road is residential (Stonebridge) and agricultural. Along State Road south of Ellsworth Road is either undeveloped or commercial, including a research and business park: Runway Plaza. Residential areas (St. James Woods and Waterways) and a research and business park (Avis Farms) are located immediately to the south of ARB. Existing land use and zoning is illustrated in Figure 4-4 and 4-5, respectively.

The land surrounding ARB in Pittsfield Township is predominately zoned as planned unit development (PUD), business park, and light industrial (Pittsfield Township, 2009). Immediately to the west of ARB, along Lohr Road, these areas are zoned as PUD (Figure 4-5). The land east of ARB, along State Road, is zoned as either business park or light industrial (Figure 4-5). Lohr Road is a mix of residential and public facilities and public and private recreation/open space. Residential is also identified immediately south of ARB. There is also a small area identified as office south of Ellsworth Road near the northeastern airport boundary. The land adjacent to ARB, within the city limits, (north of Ellsworth Road and east of State Road) is zoned as either fringe commercial, research, or industrial (City of Ann Arbor, 2008) (Figure 4-6).

As illustrated in Figure 4-7, Pittsfield Township's future land use plan identifies the area along State Road, along most of Ellsworth Road, and immediately south of ARB as research and development (Pittsfield Township, 2008). At the corner of State Road and Ellsworth Road the area is identified as community commercial and local commercial. There is also a small area identified as office south of Ellsworth Road near the northeastern airport boundary.

JJR

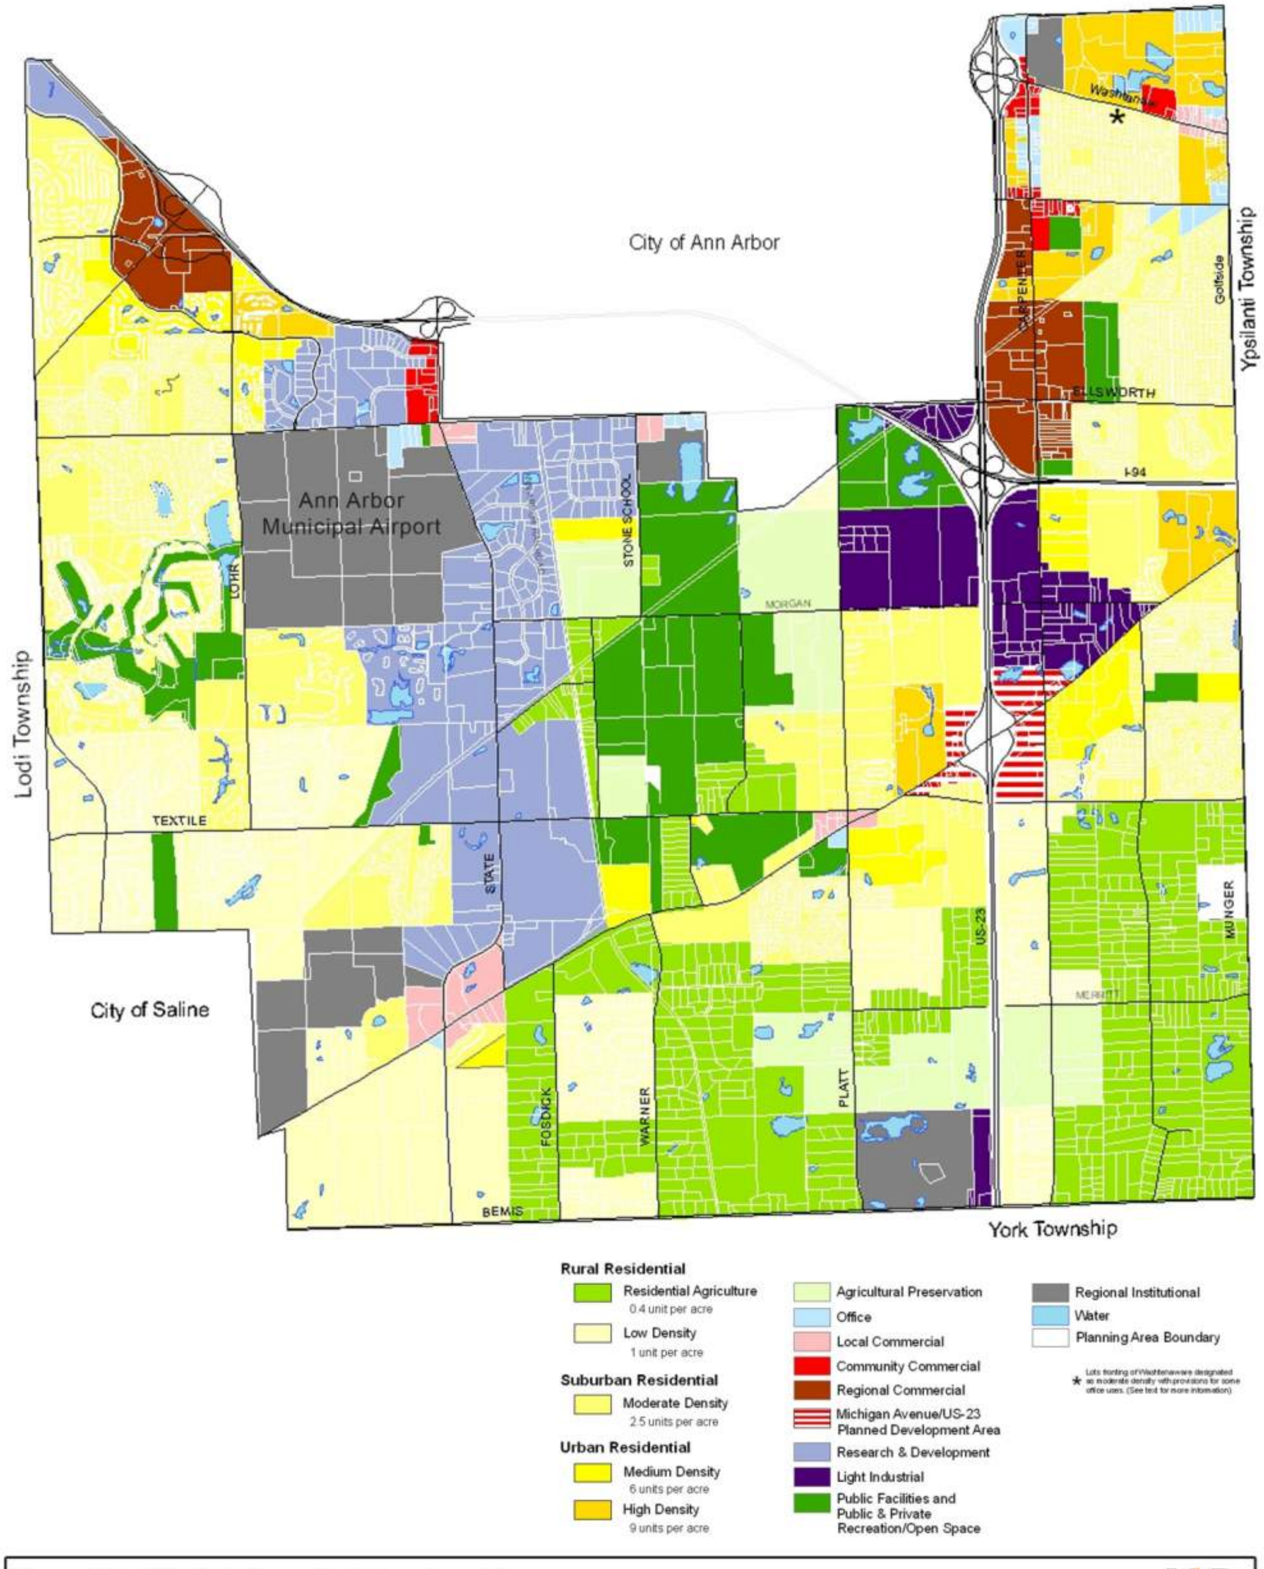

Figure 4.7: Pittsfield Township Future Land Use
Ann Arbor Municipal Airport Environmental Assessment

JJR

Consequences of the Preferred Alternative
Aircraft noise is one of the major concerns of both airport operators and airport neighbors when evaluating impacts of a proposed airport development project. Estimates of noise effects resulting from aircraft operations can be interpreted in terms of the probable effect on human activities characteristic of specific land uses. Guidelines for evaluation of land use compatibility in aircraft noise exposure areas were developed by the FAA and are presented in Table B-1 in Appendix B. The guidelines reflect the average response of large groups of people to noise and might not reflect an individual's perception of an actual noise environment. Compatible or incompatible land use is determined by comparing the predicted or measured daily noise level at a specific site with the compatibility guidelines. According to FAA, all land uses are normally compatible with aircraft noise levels below 65 DNL. For noise exposure levels greater than 65 DNL, compatibility is dependent on land use. For example, commercial and manufacturing land uses are more tolerant of higher noise levels than a hospital or church. In general, most land uses are considered incompatible when noise levels exceed 75 DNL.

If the Preferred Alternative is implemented, the 65, 70, and 75 DNL contours would all still remain within airport property. As a result, the land use within the vicinity of ARB would remain compatible with the airport under the Preferred Alternative, which involves the extension of Runway 6/24.

The FAA and MDOT have reviewed the Runway Safety Area (RSA), Object Free Area (OFA), and Runway Protection Zone (RPZ) requirements for the approach areas of Runway 6/24. Even with the implementation of the Preferred Alternative, and the shift and extension of the runway to the southwest, the RSA, OFA, and RPZ in the southwest approach area will continue to remain totally clear of obstruction and entirely on airport property. Since the runway approach areas will continue to meet all FAA and MDOT safety standards, there is no indication that the development of the Preferred Alternative will result in increased hazards to people or structures on the ground. Existing and proposed land use adjacent to and in the immediate vicinity of ARB is compatible with normal airport operations.

4.3 INDUCED SOCIOECONOMIC IMPACTS

4.3.1 Community Displacement

No land would be acquired as either fee or easement acquisition and no displacements would occur as a result of the Preferred Alternative.

Consequences of the Preferred Alternative
There would be no community displacement impacts, no residential or business displacements, and no land acquisition resulting from the Preferred Alternatives.

4.3.2 Environmental Justice

Existing Conditions

The federal government's policy on nondiscrimination in all federally funded activities formally began with Title VI of the 1964 Civil Rights Act. Title VI requires all federal agencies to ensure that "No person in the United States shall, on the ground of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance."

Further guidance was provided in 1994 with *Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*. The intent of the Executive Order is to identify and avoid disproportionately high and adverse human health or environmental effects on minority and low-income populations.

The presence of minority or low-income populations in the project area was determined by an evaluation of U.S. Census data, and Michigan State Housing Development Authority (MSHDA) data. ARB is owned and operated by Ann Arbor, yet is located in Pittsfield Township. Census data for the city and township was compared to Washtenaw County to make a determination regarding the presence of an environmental justice population.

<u>Minority Populations</u>

Race data from the 2000 U.S. Census (U.S. Census Bureau, 2009) was used to determine the presence of minority populations within the immediate area surrounding ARB. According to the Council on Environmental Quality (CEQ), minorities are defined as individuals who are members of the following population groups: American Indian or Alaskan Native, Asian or Pacific Islander, Black, not of Hispanic origin, or Hispanic (1997).

An analysis of the U.S. Census data indicates that minority populations are present near ARB, totaling 28 percent of the total population within the Pittsfield Township and 24 percent in the City of Ann Arbor. The percentage of minorities present in Washtenaw County totals 22 percent.

<u>Low-Income Populations</u>

U.S. Census economic data from the 2000 U.S. Census was used to determine the presence of low-income populations in the project area. The economic data identifies the income required to be below the poverty level and the number of people that are below that level. The U.S. Census Bureau measures poverty according to poverty thresholds, which is most simply defined as a measure of income inadequacy. This method of defining poverty thresholds was developed based on the income level that would cause a family to cut back on food expenditures sharply, assuming food expenses and non-food expenses would be cut at the same rate (Fisher, 1997).

According to the 2000 economic data, there is a percentage of the population below the poverty level near ARB, accounting for 9 percent of the total population in Pittsfield

Township and 17 percent in the City of Ann Arbor. These percentages are similar to 11 percent in Washtenaw County. Reviewing economic data at the block level indicates that in the immediate area surrounding ARB, there is a lower percentage of low-income populations, ranging from a high of 8 percent to a low of 0.7 percent.

Consequences of the Preferred Alternative

In conclusion, this project would not have a disproportionately high or adverse effect on either minority or low-income populations. All improvements at ARB would occur within the airport property. There would be no noise impacts or residential displacements. No property acquisition would occur as a result of the Preferred Alternative.

While there are not any environmental justice issues associated with the proposed improvements identified at this time, a continuing effort would be made to identify disproportionately high and adverse impacts to minority and low-income populations as this project advances. If such impacts are identified, every effort would be made to involve impacted groups in the project development process and to avoid or mitigate these impacts. A public hearing would be held to allow the public, local officials, and agencies to comment on the proposed improvements. The hearing would be advertised according to FAA guidelines. Section 5 provides a detailed discussion of all public involvement activities.

4.3.3 Community Cohesion and Community Facilities

Existing Conditions

As noted in Section 4.2, residential, commercial, industrial, recreational, undeveloped, and agricultural areas immediately surround ARB. The closest community facility is the Pittsfield Township Fire Station 3, which is located at 705 W. Ellsworth Road, just west of State Street. East of Fire Station 3 is the Pittsfield Community Center at 701 W. Ellsworth Road. This facility houses the Pittsfield Senior Center. Pittsfield Township Park, located south of the Senor Center, is a 7-acre park with an accessible pathway, a softball field, three t-ball fields, a playground, and picnic tables and grills. The Ann Arbor United Soccer Club operates seven soccer fields on city-owned land located at 801 Airport Road between the ARB entrance and Ellsworth Road.

Consequences of the Preferred Alternative

There would be no displacements as a result of the Preferred Alternative. All of the surrounding roads would remain open during and after construction, and there are no anticipated impacts to circulation. Noise levels would not be significantly increased and flight paths would not change. Therefore, the Preferred Alternative would not result in impacts to community cohesion or facilities.

4.3.4 Demographics

Existing Conditions

Population data for 1990 and 2000 were obtained from the U.S. Census Bureau. Historical data and the population projections for 2015 and 2025 were obtained from the

Southeast Michigan Council of Governments (SEMCOG) (SEMCOG, 2009). This information indicates that since 1970, overall, the population has grown in the Ann Arbor area (Table 4-1). Pittsfield Township has experienced the highest growth trend from 1970 through 2000 (Table 4-1). As shown, these growth trends are projected to continue through 2025 (SEMCOG, 2009).

Table 4-1
Ann Arbor Area Population (1970 – 2000) and Projections

Community	1970	1980	1990	2000	2015	2025
City of Ann Arbor	100,035	107,969	109,592	114,024	114,081	114,810
Pittsfield Township	8,073	12,986	17,668	30,167	34,969	35,750
Washtenaw County	234,103	264,740	282,937	322,895	353,327	361,715

Source: U.S. Census Bureau and SEMCOG

According to the U.S. Census, the total number of housing units has been increasing in the Ann Arbor area. In 1990, the City of Ann Arbor had 44,010 total housing units, which increased to 47,218 in 2000. Pittsfield Township had 7,794 total housing units in 1990, with an increase to 12,337 units in 2000 (Table 4-2).

Table 4-2
Summary of Demographic Data

	1990 Census		2000 Census	
	City of Ann Arbor	Pittsfield Township	City of Ann Arbor	Pittsfield Township
U.S. Census Population	109,592	17,668	114,042	30,167
Total Housing	44,010	7,794	47,218	12,337
Total Vacant Housing Units	2,353	774	1,525	520
Percent Vacant Housing Units	5%	10%	3%	4%
Total Owner Occupied Housing Units	17,996	2,791	20,685	6,620
Percent Owner Occupied Housing Units	41%	36%	44%	54%
Total Renter Occupied Housing Units	23,661	4,229	25,008	5,197
Percent Renter Occupied Housing Units	54%	54%	53%	42%
Average Household Income	$33,344	$34,639	$46,299	$61,292
Average Family Income	$50,192	$45,597	$71,293	$82,600
Per Capita Income	$17,786	$16,936	$26,419	$29,645

Source: U.S. Census Bureau

U.S. Census data indicate renter occupied housing dominates the housing stock in the City of Ann Arbor at 53 percent and owner occupied housing accounts for 44 percent. In Pittsfield Township, owner occupied housing dominates at 54 percent and renter occupied housing accounts for 42 percent.

According to U.S. Census data, average household, family, and per capita incomes within the Ann Arbor area exhibited substantial increases between 1990 and 2000 (Table 4-2). In 1990, the average household income was $33,344 in the City of Ann Arbor and $34,639 in Pittsfield Township. This increased to $46,299 in the City of Ann Arbor and $61,292 in Pittsfield Township in 2000, a change of 39 percent and 77 percent, respectively.

The per capita income showed similar trends with increases of 49 percent in the City of Ann Arbor, increasing from $17,786 in 1990 to $26,419 in 2000. Pittsfield Township increased 75 percent, from $16,936 in 1990 to $29,645 in 2000 (Table 4-2).

The racial composition of the area surrounding the airport is described in Section 4.3.2, Environmental Justice.

Consequences of the Preferred Alternative

Impacts to demographics associated with the Preferred Alternative are not expected. There would be no displacements as a result of the Preferred Alternative; therefore, little impact to the local area population, number of households, or racial make-up is anticipated. In addition, no impact to average incomes within the local area would be anticipated as a result of the Preferred Alternative.

4.3.5 Economics

Existing Conditions

Businesses within the area surrounding ARB are primarily industrial and commercial. Research and business parks that are located around the airport include:

- Valley Ranch
- Airport Plaza
- Ann Arbor Commerce Park
- Runway Plaza
- Columbia Center
- Avis Farms
- State Street Executive Park

These types of businesses often locate near airports and are dependent, or may be dependent, on the airport for transportation services.

At the airport, there are fixed-wing FBOs, a helicopter FBO, three national rental car agencies, two flying clubs, four flight schools and pilot training centers, city airport staff, FAA air traffic control tower, air taxi, aircraft sales, aviation insurance, and aviation fueling businesses.

Consequences of the Preferred Alternative
No businesses would be displaced as a result of the Preferred Alternative. Access would not be affected during airport construction. As a result, no negative economic impacts are anticipated to the surrounding businesses and the airport businesses. A positive result of the improvements is the ability for business owners to achieve improved fleet efficiency for critical aircraft my maximizing their passenger and/or cargo loads.

4.4 AIR QUALITY

Existing Conditions
Air pollutants are contaminants in the atmosphere. Many man-made pollutants are a direct result of the incomplete combustion of fuels including coal, oil, natural gas, and gasoline. The establishment of the National Ambient Air Quality Standards (NAAQS) by the Environmental Protection Agency (EPA) was directed in the Clean Air Act (CAA), and attainment and maintenance of the NAAQS was reinforced in later amendments. The goal of air quality monitoring and actions is to ensure that the air quality levels of the various pollutants do not exceed the set standards.

Under the 1990 CAA Amendments, the U.S. Department of Transportation cannot fund, authorize, or approve federal actions to support programs or projects that are not first found to conform to CAA requirements. The air quality provisions of the CAA, as amended, are intended to ensure the integration of air quality planning in all transportation-related projects.

The Air Quality Division of the Michigan Department of Environmental Quality (MDEQ) produces an Annual Air Quality Report, which outlines the attainment status of the state. According to the 2006 Air Quality Report the project study area is in attainment with the NAAQS for ambient concentrations of carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and coarse particulate matter (PM_{10}) (MDEQ, 2008).

Of growing concern is the impact of proposed projects on climate change. Greenhouse gases are those that trap heat in the earth's atmosphere. Both naturally occurring and anthropogenic (man-made) greenhouse gases include water vapor (H_2O), carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and ozone (O_3). Research has shown that there is a direct link between fuel combustion and greenhouse gas emissions. A detailed air quality report can be found in Appendix C.

Consequences of the Preferred Alternative
MDOT Bureau of Aeronautics conducted an Air Quality Study (Landrum and Brown, 1996) of general aviation airports. Seven airports were selected as case study airports. The results of the case study were used to draw conclusions for all general aviation airports. Key findings of the study revealed that typical general aviation airports generate a low level of air pollutants. Comparisons of existing conditions at various airports with future build out conditions indicate that the net change in air emissions is still below standards. The report states that proposed projects at general aviation airports are not expected to cause or contribute to any new violations of the NAAQS.

There would be no revisions to the existing roadway system as a result of the Preferred Alternative. Consequently, the air model results for the Preferred Alternative would be identical to those for the No Build Condition. Since the No Build Condition analysis shows that no sites would exceed the one-hour or eight-hour NAAQS standard, the Preferred Alternative would also have no sites exceeding the NAAQS standard.

During construction, appropriate mitigation measures, such as covering and spraying stock piles with water, should be utilized to minimize potential short term negative impacts which may be experienced locally due to fugitive dust, construction vehicle exhaust, or other fumes related to construction materials and equipment.

Based on FAA data, operations activity at the ARB represents less than one (0.1) percent of U.S. aviation activity. Therefore, assuming that greenhouse gases occur in proportion to the level of activity, greenhouse gas emissions associated with existing and future aviation activity at ARB would be expected to represent less than 1 percent of U.S.-based greenhouse gases. Therefore, we would not expect the emissions of greenhouse gases from this project to be significant.

4.5 WATER RESOURCES

4.5.1 Surface Hydrology

Existing Conditions
An unnamed steam located on the ARB property (Figure 4-8) flows south through an open ditch. It is enclosed in a concrete culvert south and west of the existing runway. It then flows east through an open ditch ultimately to the Wood Outlet Drain to the south. The upstream drainage area of approximately 0.5 square miles north and west of the airport flows through multiple subdivisions and business parks prior to entering the airport property. The stream appears to be perennial in nature with low flow water levels 8 to 10 inches deep. The streambed is 2- to 3-feet wide and is composed mostly of silty clay. While the channel is deeply incised in some locations, flows are expected to be variable as indicated by eroded banks 2- to 3-feet high throughout the corridor. Water quality is likely degraded as surface water contributions from runoff over turf and numerous storm outlets draining adjacent parking lots and streets are common.

Consequences of the Preferred Alternative
The stream would not be altered as a result of the improvements at ARB. The enclosure would not be extended.

The amount of impervious surface on site would increase slightly due to the extension of the runway and the taxiway from the existing 7 percent of the 837 acres site to 7.4 percent. An approved Storm Water Pollution Prevention Program is in place for ARB. Implementation of appropriate best management practices (BMPs) would continue to control the rate of stormwater runoff and maintain water quality standards.

Figure 4.8: Existing Water Resources and Land Cover
Ann Arbor Municipal Airport Environmental Assessment

NOT TO SCALE

4.5.2 Geology, Groundwater, and Soils

Existing Conditions
Millstein (1987) identified nine bedrock formations in Washtenaw County. Coldwater Shale is the primary bedrock in central Washtenaw County, composed primarily of shale, with some limestone, dolomite, sandstone, and siltstone.

There are 14 soil mapping units in the project area (USDA, 1997). The soils south of the runway are predominately hydric soils, either Palms muck, Adrian muck, or Edwards muck. Matherton sandy loam, Fox sandy loam, and Wasepi sandy loam are the soils located in the area of the runway and to the north of the runway. The muck soils have a high water table with water often at the surface. The Fox soils have a water table at a depth of greater than 6-feet, and the Matherton and Wasepi soils have a water table at 1- to 2-feet below the surface (USDA, 1997).

ARB is located in a wellhead protection area known as the Three Fires Aquifer Wellhead Protection Area. The Three Fires Aquifer supplies the City of Ann Arbor with a portion of their public drinking water supply. Three of the City's municipal wells are located at ARB. The purpose of the protection area is to prevent contamination of the aquifer.

The City of Ann Arbor has plans to construct a new water supply line from the wells. No new wells are planned at this time.

Consequences of the Preferred Alternative
Surface and subsurface geological conditions do not represent a constraint to implementation of the Preferred Alternative and, consequently, would not be impacted. Based on coordination with the City of Ann Arbor, the proposed runway extension would not impact the water supply wells or the new water supply line (Bahl, 2009).

4.6 SECTION 4(f) RESOURCES

Existing Conditions
Section 4(f) of the Department of Transportation Act (1966) specifies that publicly-owned land, such as a park, recreational area, or wildlife and waterfowl refuge, of national, state, or local significance, or any land from a historic site of national, state, or local significance, may not be used for transportation projects unless there is no other prudent and feasible alternative. If there are no other prudent and feasible alternatives, the proposed project must include all possible efforts to minimize impacts to Section 4(f) properties.

A Pittsfield Township park is located along the northern airport property line. There are no historic resources within ARB and its surrounding areas that are considered Section 4(f) resources. The review process that has been used for evaluating the Section 4(f) properties has included coordination with the Michigan State Historic Preservation Office (SHPO) (Appendix D), and an archaeological resource survey (CCRG, 2009) that identified historic resources either currently listed on, or potentially eligible for listing on, the National Register of Historic Places (NRHP).

Consequences of the Preferred Alternative
The Preferred Alternative would not result in impacts to a publicly owned park, recreation area, or refuge, and ARB has coordinated with the SHPO to determine that there are no historic, archeological or architectural resources within the airport and its surrounding areas (Appendix D). The Pittsfield Township park would not be impacted and would not be acquired. No impacts to Section 4(f) resources are anticipated from the Preferred Alternative.

4.7 HISTORIC, ARCHEOLOGICAL, AND ARCHITECTURAL RESOURCES

Existing Conditions
An evaluation was conducted to determine the need for archaeological and/or above-ground surveys at ARB (CCRG, 2009). The evaluation included a field review of the area of the proposed improvements, a review of state archaeological files and above-ground resource files, and shovel tests at the site.

Consequences of the Preferred Alternative
ARB has coordinated with the SHPO to determine the presence of any historic, archeological, or architectural resources within the airport and its surrounding areas (Appendix D). Based on the file review and state files, no impact to historic, archeological or architectural resources is anticipated.

4.8 BIOTIC COMMUNITIES

Existing Conditions
Botanical communities within ARB and its immediately surrounding areas include active agricultural fields, unmown grassy meadows, a perennial stream, wet meadow, and a forested wetland. The developed portions of the airport property consist of structures, paved surfaces, a runway, access roads and parking lots, and maintained grassy areas.

Three predominant communities were observed on the property: upland, wet meadow, and forest (Figure 4-8). Plant species lists for these areas are shown in Appendix E. Most of the airport property and surrounding land has been altered by human activities. The least altered biotic communities are the grassy meadows surrounding the runway and the forested wetland to the south. The grassy meadow areas are only mowed periodically because of an agreement with the local Audubon Society.

The area at the end of the runway, where proposed expansion would occur, is kept mowed and the dominant plants in this area consisted of old field weeds and grassy species, with disturbed areas of bare dirt. Plants include rough-fruited cinquefoil (*Potentilla recta*), Canada thistle (*Circium arvense*), and an unidentified grass.

The sides of the stream contained upland weedy herbaceous species such as sweet clover (*Melilotus officinalis*), smooth brome (*Bromus inermis*), giant ragweed (*Ambrosia trifida*), Virginia creeper (*Parthenocissus quinquefolia*), lamb's quarters (*Chenopodium album*), riverbank grape (*Vitis riparia*), dame's rocket (*Hesperis matronalis*), teasel (*Dipsacus fullonum*), cow parsnip (*Heracleum maximum*), yellow goatsbeard (*Tragopogon pratensis*), yarrow (*Achillea millifolium*), a few reed canary grass, wheat or rye (*Triticum* or *Secale* spp), and mixed upland and wetland trees such as American elm (*Ulmus americana*), box elder (*Acer negundo*), staghorn sumac (*Rhus typhina*), Russian olive (*Eleagnus angustifolia*),buckthorn (*Rhamnus catharticus*) cottonwood (*Populus deltoides*), bur oak (*Quercus macrocarpa*), and American linden (*Tilia americana*).

Several examples of wildlife were observed, including robins (*Turdus migratorius*), goldfinch (*Carduelis tistis*), purple martins (*Progyne subis*), killdeer (*Charadrius viciferus*), and a mating pair of redtail hawks (*Buteo jamaicensis*). Other observations include evidence of rodent tunneling (field mice or voles) and pheasants (*Phasianus colchicus*) that were heard calling. Airport staff stated that coyote (*Canis latrans*) and white tail deer (*Odocoileus virginianus*) have been observed on the airport property as well as wild turkeys (*Meleagris gallopavo*). A comprehensive list of all the bird species observed by the Audubon Society at ARB is included in Appendix F.

Consequences of the Preferred Alternative

Implementation of the Preferred Alternative would require grading and construction of the extended runway. The areas to be impacted by grading are currently maintained and mowed for ARB or leased as agricultural land. A portion of the grading for the new taxiway near State Road would be in an area currently under restricted mowing per the agreement with the Audubon Society. The remaining areas would continue to be maintained with limited mowing as agreed by ARB and the Audubon Society. No trees would be cut or directly impacted by construction due to height obstructions.

The overall populations of wildlife species utilizing the area are not anticipated to be impacted as the maintenance of open grassy areas would continue. Wildlife may be temporarily impacted due to the presence of construction equipment in the vicinity.

4.9 THREATENED AND ENDANGERED SPECIES

Existing Conditions

Coordination with the US Fish and Wildlife Service (USFWS) (Appendix D) indicated that this agency has no records of federal-listed endangered, threatened, or otherwise significant species, natural plant communities, or natural features in the vicinity of ARB. The Michigan Department of Natural Resources (MDNR) indicated that Henslow's sparrow, state endangered, (*Ammodramus henslowii*) and Grasshopper sparrow, state special concern, (*Ammodramus savannarum*) are known to occur on or in the vicinity of the area. The presence of these species has been confirmed by the Audubon Society during their annual counts at ARB over the last three years.

All habitats within the project area have been impacted to varying degrees by human activities. No plant species listed as threatened or endangered by the MDNR or USFWS were found during the botanical survey conducted in June 2009.

Consequences of the Preferred Alternative

No known legally protected plants were observed within the project area. Grading for the new taxiway near State Road would be in an area currently under restricted mowing per the agreement with the Audubon Society. ARB revises the boundaries of this mowing agreement annually, with the Audubon Society, based on their most current bird count data. There would be no grading within agreed upon restricted mowing areas during the breeding season for either species which extends through late August for Henslow's sparrow and mid-July for Grasshopper sparrow.

4.10 WETLAND RESOURCES

Existing Conditions

Field surveys conducted in June 2009 revealed the presence of wetland vegetation at the east end of the runway. The MDEQ conducted a field visit in July 2009 to confirm whether the area would be classified as a wetland (Appendix D). A 5-acre area was reviewed for dominate vegetation, hydrology, and soils. A wetland was identified; however, the wetland does not constitute a wetland that is regulated by the state. The wetland is further than 500-feet from an inland lake, river, or stream, is less than 5 acres in size, and there is no surface connection with other wetlands in the area (MDEQ, 2009).

This area was a mix of mostly wetland species and scattered upland species, including reed canary grass (*Phalaris arundinacea*), sedge (*Carex granularis*), swamp milkweed (*Asclepias incarnata*), dandelion (*Taraxicum officinale*), sowthistle species (*Sonchus* sp.), buckthorn (*Rhamnus cathartica*), curly dock (*Rumex crispus*), and either goldenrod or aster species (*Solidago* or *Aster* sp.).

Consequences of the Preferred Alternative

The wetland at the east end of the runway would not be impacted by the proposed improvements, but it would be adjacent to the taxiway. This area would be protected with silt fence during construction and the 25-foot wetland buffer would be restored following construction.

4.11 FLOODPLAINS

Existing Conditions

An unnamed perennial stream is located within ARB, flowing to the south and ultimately connecting to the Wood Outlet Drain south of the airport. In accordance with FAA Order 5050.4B *Airport Environmental Handbook*, a review of the floodplains in the area and the impacts that may occur as a result of the development was undertaken.

Consequences of the Preferred Alternative

Review of the Federal Emergency Management Agencies (FEMA) flood boundary maps identified a floodplain boundary for the stream. The proposed grading for the expansion would not occur within the designated floodplain boundary and no fill would be placed in the floodplain. Therefore, there would be no impacts to the floodplain located within ARB.

4.12 COASTAL ZONE MANAGEMENT PROGRAM

The area surrounding ARB is not located within a coastal zone management area and, thus, the Preferred Alternative would have no impact on the Coastal Zone Management Program.

4.13 COASTAL BARRIERS

The area surrounding ARB is not located within a coastal zone management area, and the Preferred Alternative would have no impact on coastal barriers.

4.14 WILD AND SCENIC RIVERS

There are no waterbodies within the immediate vicinity of ARB that are designated as state or federal Wild and Scenic Rivers; therefore, the Preferred Alternative would have no impact on Wild and Scenic Rivers.

4.15 FARMLAND

ARB currently leases 168 acres of its property to a local farmer. If the Preferred Alternative is implemented, 18 acres of land would no longer be farmed. U.S. Department of Agriculture (USDA) requires a form, AD 1006, to be filed when agricultural land would be impacted. This agency estimates the total acres of prime and unique farmland, the total acres of statewide and local important farmland, and the percentage of farmland in the county to be converted. The relative overall value of farmland to be converted is also provided.

Prime farmlands are identified as land that has the best combination of physical and chemical characteristics for producing food, forage, fiber, and oilseed crops (USDA, 1983). Unique farmland is land, other than prime farmland, that has special characteristics, such as unique soil types and topographic features, which make it suitable for the production of specific high value crops. Land classified as prime or unique farmland is not necessarily actively farmed, it also may include other vegetated lands such as fallow fields and woodlands. Farmland of local importance includes those lands with nearly prime farmland characteristics that could economically produce high yields when treated and managed according to modern farming methods (USDA, 1983).

Consequences of the Preferred Alternative

ARB would not be acquiring any farmland for the proposed project. Based on coordination with the Washtenaw County Natural Resources Conservation Service (NRCS) (Appendix D), some prime farmland and farmland of local importance would be impacted by this project. The limits of grading have been minimized to the extent possible. The land outside of these limits would continue to be leased as farmland.

4.16 ENERGY SUPPLY AND NATURAL RESOURCES

Development of the Preferred Alternative would have the potential to increase the amount of air traffic utilizing ARB, which can potentially result in an increase in the amount of airplane fuel distributed by the airport and used by aircraft at the facility. A small amount of additional fuel would be used during construction of the runway and taxiway. However, these minimal increases in gas/fuel consumption are not considered significant.

ARB is installing approximately 250 LED taxiway lights which would decrease facility energy usage.

4.17 LIGHT EMISSIONS

The Preferred Alternative includes the addition of edge lights and the relocation of runway end identifier lights (REILS) to the end of the newly extended runway. Light emission impacts to adjacent homes would be minimized because lights within the light lane would be directed upwards. The REILS would be closer to Lohr Road and the adjacent homes; however, the existing lights would be replaced with a smaller LED unit.

Light emissions created by the Preferred Alternative are not considered significant. However, if impacts are noted, appropriate mitigation for the impacts would occur. Examples of mitigation include shielding the lights from below so that the light is reflected up to the sky or reducing light intensities, if the FAA makes a determination that a reduction would not affect the safety of the aircraft.

4.18 SOLID WASTE IMPACTS

Minimal waste would be generated during construction of the Preferred Alternative. No building demolition would occur. The existing runway and taxiway would remain and new material would be used for the extended portions of the runway and taxiway. The portions of the runway that would no longer be used would still exist, but marked accordingly. The nearest operational landfill is the Arbor Hills Landfill in Salem Township on 6 Mile Road in Northville, which is a Type II landfill that accepts household, commercial, and non-hazardous industrial waste. The Preferred Alternative would have minimal anticipated impact on nearby landfill facilities. In addition, these facilities have no impact on the Preferred Alternative given the distance separating them from ARB.

4.19 EXISTING AND FUTURE TRAFFIC CONDITIONS

The Preferred Alternative would not require either temporary or permanent closure of local roads surrounding ARB. During construction, it is expected that minor increases in traffic would occur from the construction crews traveling to and from ARB. Overall, the Preferred Alternative would have no significant impact on existing or future traffic volumes in the surrounding area.

4.20 CONSTRUCTION IMPACTS

The Preferred Alternative may result in temporary, localized air, water, and noise quality impacts during construction. Construction documents would identify specific environmental control methods to minimize air and water quality impacts. Air quality impacts, such as fugitive dust and exhaust from construction equipment, may be minimized by seeding disturbed areas, covering haul trucks, and wetting down construction areas. Sediment and erosion control measures would be used to minimize any water quality impacts during construction. Construction would comply with FAA specifications (FAA Advisory Circulars 150/5370-2C – Operational Safety on Airports During Construction, and 150/5370-10A Changes 1-12 – Standards for Specifying Construction of Airports), and State of Michigan regulations would be followed as required to prevent air pollution.

4.21 CONTAMINATED SITES REVIEW

Existing Conditions
A review of federal and state records was completed to identify known properties listed by state and/or federal agencies as either contaminated or sites of environmental concern (EDR, 2009). The intent of this review was to assist in the evaluation of study alternatives; the review was not a Phase I Environmental Site Assessment in accordance with American Society of Testing and Materials (ASTM) (Standard E1527-94). Several mapped sites were found on ARB or within the immediate area (within a one mile radius of the airport). These mostly include underground and above-ground storage tanks and small quantity generators.

There are no underground storage tanks on the airport property. ARB has two small (approximately 250 gallon) tanks that are used for maintenance operations. The City of Ann Arbor does not store or sell aviation fuel products.

The University of Michigan Flyers have an aboveground tank (approximately 3,000 gallons) with avgas (100LL fuel). Avfuel has three large aboveground tanks at ARB (approximately 20,000 gallons each) with avgas (100LL fuel) and Jet A fuel. Avfuel stores the aviation fuel and the FBO's sell it.

All fuel near the airport property is stored in tanks in accordance with MDEQ licensure guidelines and all tanks currently meet regulations.

Consequences of the Preferred Alternative

The Preferred Alternative is not anticipated to have an impact on known properties listed by state and/or federal agencies as either contaminated or sites of environmental concern. There would be no impacts to the fuel storage tanks during construction. Further, if contaminated soil is encountered during construction, proper disposal methods and construction procedures that minimize disturbance of contaminated soils would be utilized.

Section 5.
Environmental Consequences - Other Considerations

5.1 MITIGATION MEASURES

General Area and Project Information
ARB is planning to shift and extend Runway 6/24 and the parallel taxiway by approximately 800-feet.

Noise
The FAA's INM Version 7.0a was used to develop noise exposure contours in order to assess the noise impacts associated with the proposed extension of Runway 6/24. No homes or noise sensitive land uses are located within the 65 DNL contour for the Preferred Alternative future conditions. The Preferred Alternative is not expected to have any significant aircraft noise impacts; therefore, no mitigation is proposed.

Social Impacts and Community Disruption
There would be no land acquisition and no displacements as part of this project. If acquisition was required, it would follow the Uniform Relocation Assistance Act of 1970, as amended, and FAA AC 150/5100-17.

Wetland Impacts
Impacts to affected wetlands would require mitigation under Section 404 of the Clean Water Act, Executive Order 11990, and Part 303 of the Natural Resources and Environmental Protection Act (P. A. 451). When unavoidable impacts occur to regulated wetlands, both state and federal regulations require compensatory mitigation. The intent of the mitigation is the replacement of the lost functions of the wetland areas to be displaced. There would be no wetland impacts as a result of this project; therefore, no mitigation is required.

Threatened and Endangered Species
No known threatened or endangered species were identified within the project site; therefore, no mitigation is required.

5.2 DEGREE OF CONTROVERSY

During the course of this project, there has been input by local citizens regarding the need for the project and the potential impacts. Most of the input received focused on the need for the project and how it potentially would impact adjacent homes. A Citizen's Advisory Committee (CAC) was formed (see Section 6.2). These topics were presented and discussed during the CAC meetings. A public hearing would be held during the public comment period to allow the public an opportunity to comment on the proposed improvements and the EA. A more detailed discussion of public involvement activities can be found in Section 6.2.

Section 6.
Agency Coordination and Public Participation

Agency coordination was initiated early in this study. Input and feedback from agency representatives for this project was solicited via consultation and coordination with local, state, and federal regulatory and resource agencies, and the CAC. The public would be asked to provide feedback at a public hearing that would be held in early 2010.

6.1 AGENCY COORDINATION

Early agency coordination for the project began in 2009 with local, state, and federal agencies regarding issues such as threatened and endangered species, wetlands, farmland, and archeological and architectural resources. This has included consultation with the U.S. Fish and Wildlife Service (USFWS); U.S. Department of Agriculture (USDA); Natural Resources Conservation Service (NRCS); State Historic Preservation Office (SHPO); Michigan Department of Natural Resources (MDNR); U.S. Environmental Protection Agency (USEPA); and the Michigan Department of Environmental Quality (MDEQ) (Appendix D). Staff from MDOT – Airports Division and FAA – Detroit Airports District Office have also been consulted throughout the project.

In the project planning phase, coordination and correspondence has occurred with MDEQ. MDEQ conducted a site visit and a wetland delineation at ARB and provided a letter and wetland report documenting their findings (Appendix D).

Local tribes were also contacted. Response letters are provided in Appendix D.

6.2 PUBLIC PARTICIPATION

6.2.1 Citizen's Advisory Committee

The CAC was formed in spring 2009 and is comprised of 14 individuals representing a variety of affiliations including: local residents, local commercial and business establishments, pilots, and representatives from the City of Ann Arbor, and Pittsfield Townships. The CAC was formed to receive input from CAC members on project issues, to inform them of project activities and events, and to assist CAC members in communicating project activities to each member's constituents (affiliated organizations). Public participation was formally initiated with the first CAC meeting held in May 2009. This meeting focused on the proposed improvements to ARB, the purpose and need for these changes, and project history. At that meeting, questions and comments from CAC members included primarily on project justification and the history of the project.

The second CAC meeting was held in July 2009, and provided an update on the noise analysis, historic resources, plant communities, and wetlands. An overview of the User Survey Report was also provided. During this meeting, each CAC member was asked to provide an update on what they have been hearing from their constituency.

A third CAC meeting will be held in early 2010. This meeting will provide an update on the environmental studies along with a preview of the public hearing. Meeting summaries and a list of invitees and attendees for each CAC meeting were mailed to all meeting participants. A list of CAC members is provided in Appendix G.

6.2.2 Public Hearing

The Draft EA will be published and available for review for 30 days prior to the public hearing. The public comment period closes 10 days after the public hearing date. A legal notice will be published in the local Ann Arbor newspaper to announce the availability of the Draft EA and the date, time, and location of the public hearing.

Copies of the Draft EA will be forwarded to appropriate local, state, and federal regulatory and resource agencies and will be available for public review at ARB, Ann Arbor City Hall, Pittsfield Township Municipal office, and the Ann Arbor Public Library.

A public hearing on this study will be held in early 2010. The format of the public hearing will be an informal open house. The purpose of this hearing will be to provide the general public with information regarding the study purpose and need, alternatives considered, and selection of a Preferred Alternative. Exhibits and display stations will be set up to cover each aspect of the project, and the study team will be available to personally respond to questions regarding the proposed project. A public hearing handout will also be provided to attendees. Opportunities will be provided to submit both written and oral comments. All of the public and agency comments received will be reviewed and summarized in the Final EA.

Section 7. Conclusion

Based on the information in this EA and coordination with local, state, and federal regulatory agencies and the public, it is anticipated that this project will have no significant impact on the natural or human environment. If review and comment by the public and interested agencies support this determination, this EA will be forwarded to the Michigan Department of Transportation’s Bureau of Aeronautics and Freight Services and the Federal Aviation Administration with a request that a Finding of No Significant Impact (FONSI) be prepared and location/design approval be granted.

Section 10. Glossary

ACIP – Airport Capital Improvement Plan **–** The ACIP is a document that serves as the primary planning tool for identifying and prioritizing critical airport development and associated capital needs.

ADG – Airplane Design Group

ALP – Airport Layout Plan **–** The ALP is a set of drawings or an individual drawing that identifies future development at the airport. The ALP is part of the airport Master Plan.

ARB – Ann Arbor Municipal Airport

ARC – Airport Reference Code– The ARC is a coding system developed by the FAA to relate airport design criteria to the operational and physical characteristics of the airplane types that will operate at a particular airport.

ATCT – Air Traffic Control Tower

DNL – Day/Night Level (Noise)

EA – Environmental Assessment

EJ – Environmental Justice– An EJ is an Executive Order intended to identify and avoid disproportionately high and adverse human health or environmental effects on minority and low-income populations.

FAA – Federal Aviation Administration

Farmlands of State or Local Importance – The Natural Resources Conservation Service (NRCS) defines these farmlands as: "Those lands that are nearly prime and that economically produce high yields when treated and managed according to modern farming methods. Some may produce as high a yield as prime farmlands, if conditions are favorable." (USDA, 1983.)

FBO – Fixed Base Operator

FEMA – Flood Emergency Management Administration

FONSI – Finding of No Significant Impact

IFR – Instrument Flight Rules

ILS – Instrument Landing System

INM – Integrated Noise Model

MALSF - Medium Intensity Approach Lighting System with Sequenced Flashers

MASP – Michigan Airport System Plan

Master Plan – The airport Master Plan is a long-range planning (i.e., generally good for 20 years) document that inventories airport conditions, identifies facility requirements, and recommends future development. The Master Plan includes written text, as well as the ALP drawing(s) (see Airport Layout Plan above).

MDEQ – Michigan Department of Environmental Quality

MDNR – Michigan Department of Natural Resources

MDOT – Michigan Department of Transportation - Airports Division

Mitigation – Compensatory measures for impacts occurring as a result of an activity

MNFI – Michigan Natural Features Inventory

MSHDA – Michigan State Housing Development Authority

MTOW – Maximum Takeoff Weight

NAAQS – National Ambient Air Quality Standards

NEPA – National Environmental Policy Act

NPIAS – National Plan of Integrated Airport Systems

NRCS – Natural Resources Conservation Service (formerly the Soil Conservation Service)

ODALS - Omni-Directional Approach Lighting System

Prime Farmland – The NRCS has designated prime farmland as: "Land that has the best combination of physical and chemical characteristics for producing food, forage, fiber, and oilseed crops. The land could be crop, pasture, range, forest, or other uses, but does not include urban built-up land or water bodies, since these two are considered irreversible uses. It has soil quality, growing season, and moisture supply needed to economically produce/sustain high yields when treated and managed according to modern farming methods, including water management." (USDA, 1983.)

REILS – Runway End Identifier Lights.

RPZ – Runway Protection Zone – The RPZ is a three dimensional trapezoid, which controls the height of objects within the boundaries of this surface. These areas vary in size, depending on the type of approach category of a particular runway. The RPZ does not have to be cleared or graded, but does require air rights.

RSA – Runway Safety Area – The RSA is a prepared or suitable surface area that surrounds the runway in order to reduce the risk of damage to airplanes and injury to pilots and passengers in the event of an undershoot, overshoot, or excursion from the runway. This area, which parallels the runway, is 500 feet wide and preferably extends 1000 feet from the end of runway. The RSA must be clear of all objects and graded for aircraft and emergency vehicle use.

SHPO – State Historic Preservation Office

Site of Environmental Concern – An identified site of potential contamination due to the presence or handling of hazardous materials on site (e.g., site containing underground storage tanks).

Site of Environmental Contamination – Site of known contamination which falls under Michigan's Natural Resources and Environmental Protection Act 451, Part 201 (formerly Part 307) PA of 1994.

TAF – Terminal Area Forecast

Unique Farmlands – The NRCS has defined unique farmlands as: "Land other than prime farmland that is used for the production of specific high value food and fiber crops. These lands have a special combination of factors needed to economically produce sustained high quality yields of a specific crop when treated and managed according to modern farm methods. The special factors that make the land unique include soil quality, growing season, temperature, humidity, elevation, aspect, moisture supply, or other conditions such as nearness to market that favor growth of a specific crop. Moisture supply is the form of stored moisture, precipitation, or a developed irrigation system." (USDA, 1983.)

USEPA – United States Environmental Protection Agency

USFWS – United States Fish and Wildlife Service

VFR – Visual Flight Rules

AIRPORT USER SURVEY REPORT

ANN ARBOR MUNICIPAL AIRPORT (ARB)
ANN ARBOR, MICHIGAN

July 2009

An airport user survey for Ann Arbor Municipal Airport (ARB) has been conducted by the Michigan Department of Transportation - Airports Division (MDOT). The purpose of the survey was to determine if there is justification of need for a proposed extension of primary Runway 6/24, based on current MDOT and Federal Aviation Administration (FAA) standards.

Runway 6/24 is presently 3,505 feet in length and 75 feet wide. The current Airport Layout Plan shows a proposed extension of this runway to an ultimate length of 4,300 feet.

Planning activities associated with the potential development of the extension began in 2007, and in that year the airport manager was requested to collect supporting aircraft operational data. Other data sources listed below were also examined as part of the survey analysis. In order to maintain consistency among the various data sources, only operational data from year 2007 was analyzed.

Based aircraft operational information was collected by Mr. Matthew Kulhanek, airport manager at ARB. The information provided was accurate as of October 18, 2007.

Itinerant (visiting) aircraft operational data was collected by the two Fixed Base Operators (FBOs) that are located on the airport. The FBOs are Solo Aviation and Ann Arbor Aviation Center. Their data collection processes were conducted over a six-month time frame, ranging from April 1, 2007 to September 30, 2007.

Records of operational activity at ARB for the entire calendar year 2007 were also obtained from the FlightAware flight tracking resource agency. FlightAware is a company that records and offers flight tracking information for both private and commercial air traffic in the United States.

During the user survey analysis, every aircraft-type listed in the various data sources was categorized according to FAA approach category, design group, and weight classifications. The various aircraft classifications and associated dimensional standards are shown on the next page. All of the operational records were carefully screened, counted, and cross-checked in order to eliminate the possibility of counting the same aircraft twice, if it was listed in more than one data source.

AIRCRAFT CLASSIFICATIONS (FAA):

APPROACH CATEGORY:

Category A:	Approach speed less than 91 knots.
Category B:	Approach speed 91 to 120 knots.
Category C:	Approach speed 121 to 140 knots.
Category D:	Approach speed 141 to 165 knots.
Category E:	Approach speed 166 knots +

DESIGN GROUP:

Group I:	Wingspan up to but not including 49 feet, tail height up to 20 feet.
Group II:	Wingspan 49 feet up to but not including 79 feet, tail heights 20 to 30 feet.
Group III:	Wingspan 79 feet up to but not including 118 feet, tail heights 30 to 45 ft.
Group IV:	Wingspan 118 feet up to but not including 171 feet, tail heights 45 to 60 ft.
Group V:	Wingspan 171 feet up to but not including 214 feet, tail heights 60 to 66 ft.
Group VI:	Wingspan 214 feet up to but not including 262 feet, tail heights 66 to 80 ft.

SMALL AIRPLANE:

An airplane of 12,500 lbs. or less maximum certificated takeoff weight.

LARGE AIRPLANE:

An airplane of more than 12,500 lbs. maximum certificated takeoff weight.

BASED AIRCRAFT ANALYSIS:

According to the Based Aircraft survey data compiled on October 18, 2007, there were 166 aircraft based at ARB. Five were helicopters, 152 were of the A-I classification, eight were of the B-I classification, and one (the only jet based at the airport) was of the B-II Large (greater than 12,500 lbs. maximum certificated takeoff weight) classification. An estimated 200 annual operations were performed by the jet aircraft.

An operation can be either a takeoff or a landing. Therefore, if a based aircraft departs the airport, and later returns, this equals a total of two operations even though it may have only been one actual flight.

Aircraft by FAA Classification:		Estimated Annual Operations:
Helicopter:	5	N/A
A-I:	152	*
A-II:	0	*
B-I:	8	*
B-II Small (<12,500 lbs.):	0	0
B-II Large (>12,500 lbs.):	1	200
C-I Large:	0	0
C-II Large:	0	0
Total:	166	

* Note: Estimated Annual Operations for A-I, A-II, and B-I classifications were not calculated as part of this analysis, as they are not a factor to the Critical Aircraft determination, nor do they provide justification for the proposed extension of the runway.

ITINERANT AIRCRAFT ANALYSIS:

Itinerant (visiting) aircraft are those that perform operations at a particular airport, but are actually based somewhere else. Itinerant aircraft information for ARB was compiled by the two FBOs that are located on the airport - Solo Aviation and Ann Arbor Aviation Center. The data sources were the pilot registration logs (airport registers) from each of their businesses. Since pilot sign-in is strictly voluntary, the registers do not account for all itinerant activity at ARB.

During the user survey analysis, two operations were awarded to each aircraft listed on the FBO airport registers. This is due to the FAA standard of considering each landing and subsequent takeoff by each visiting aircraft, two separate operations. Also, since the data was collected over a six-month time frame (April 1, 2007 to September 30, 2007) instead of a full year, operations were again multiplied by two in order to achieve an equivalent annual operational rate for the full calendar year 2007. This resulted in a total multiplier factor of four for each aircraft listed on the registers. This method is standard procedure during the analysis phase of all airport user surveys.

Data collected from the two FBOs is shown in the following tables. Note that aircraft operations that are already accounted for in the FlightAware database have not been included in the number of estimated annual operations listed in these tables. None of the estimated annual operations listed by the Solo Aviation FBO were performed by jet aircraft. Thirty-six of the operations listed by the Ann Arbor Aviation Center FBO were performed by jets.

FBO – Solo Aviation

Aircraft by FAA Classification:		Estimated Annual Operations:
Helicopter:	1	N/A
A-I:	183	*
A-II:	3	*
B-I:	40	*
B-II Small (<12,500 lbs.):	2 **	8 **
B-II Large (>12,500 lbs.):	2 **	8 **
C-I Large:	0	0
C-II Large:	0	0
Total:	231 **	

ITINERANT AIRCRAFT ANALYSIS (continued):

FBO – Ann Arbor Aviation Center

Aircraft by FAA Classification:		Estimated Annual Operations:
Helicopter:	3	N/A
A-I:	205	*
A-II:	13	*
B-I:	59	*
B-II Small (<12,500 lbs.):	5 **	20 **
B-II Large (>12,500 lbs.):	7 **	28 **
C-I Large:	3 **	12 **
C-II Large:	1 **	4 **
Total:	296 **	

* Note: Estimated Annual Operations for A-I, A-II, and B-I classifications were not calculated as part of this analysis, as they are not a factor to the Critical Aircraft determination, nor do they provide justification for the proposed extension of the runway.

** Note: Aircraft numbers and Estimated Annual Operations shown have been corrected to avoid duplication of records already included in the FlightAware database.

FLIGHTAWARE DATABASE ANALYSIS:

As stated earlier, FlightAware is a company that records and offers flight tracking information for both private and commercial air traffic in the United States. The company maintains records of all flight activity for which Instrument Flight Rule (IFR) flight plans have been filed by pilots. The company does not keep records of flight activity that is conducted without flight plans under Visual Flight Rule (VFR) conditions.

Aircraft owners are allowed the opportunity to block specific information from the FlightAware database for security and/or privacy reasons. Unfortunately, the aircraft-types, owner or corporate names, and aircraft registration numbers are not listed in the database when aircraft owners elect to block their information. Origin and destination airport locations and dates of flights are still listed in the database for the blocked operations.

FlightAware provided records that were associated with flight activity to and from ARB during the entire calendar year 2007. Out of over 4,300 records of flight operations, 274 had blocked information. Since the FlightAware records do not include VFR flight activity, and do not include specific aircraft information for the blocked operations, they do not provide a complete history of all activity at the airport.

Judging by the distant locations associated with many of the blocked operations, some of the aircraft flown were likely of the larger categories. However, since the aircraft-type was not provided for these operations, none of them are included in the annual operations listed below. Had aircraft-type information been available for the blocked operations, the resulting operational numbers would likely have been higher.

Annual operations for all classifications of B-II and greater were calculated and are listed in the table shown below. Sixty-nine of the annual operations listed in the FlightAware database were performed by jet aircraft.

FAA Classification:	Annual Operations Included in Database:
B-II Small (<12,500 lbs.):	265
B-II Large (>12,500 lbs.):	85
C-I Large:	0
C-II Large:	0

COMBINED TOTALS OF ALL DATA SOURCES FOR YEAR 2007:

FAA Classification:	Estimated Annual Operations:
B-II Small (<12,500 lbs.):	293
B-II Large (>12,500 lbs.):	321
C-I Large:	12
C-II Large:	4

TOTAL ESTIMATED ANNUAL OPERATIONS USED IN DETERMINATION OF CRITICAL AIRCRAFT CLASSIFICATION:

Total Annual Operations, "B-II Small and Greater": 630 (293+321+12+4)

Total Annual Operations, "B-II Large and Greater": 337 (321+12+4)

Total Annual Operations, "C-I Large and Greater": 16 (12+4)

Total Annual Operations, "C-II Large": 4

JET AIRCRAFT:	Estimated Annual Operations
Combined total from all classifications, including B-I:	**305**

CRITICAL AIRCRAFT DETERMINATION:

The Critical Aircraft is defined by the FAA as the most demanding aircraft-type that performs a minimum of 500 annual operations at a particular airport. In cases where the Critical Aircraft weigh less than 60,000 lbs, a classification of aircraft is used rather than a specific individual aircraft model.

As shown on the previous page, a total of **630** estimated annual operations were documented by aircraft in the "B-II Small and Greater" classification, which also includes some B-II Large, C-I Large, and C-II Large category aircraft. Since none of the greater categories had operational levels in excess of 500 at ARB, the current Critical Aircraft classification has been determined to be **B-II Small Aircraft**. Note that in establishing the 500-minimum annual operational threshold, it is standard procedure to also include operations from the greater categories in the determination of the Critical Aircraft classification.

Aircraft in the "B-II Small Aircraft" classification have approach speeds between 91 and 120 knots, wingspans between 49 and 79 feet, and maximum certificated takeoff weights of 12,500 lbs. or less. A representative aircraft of this class is the Beechcraft King Air 200, a twin-engine turboprop aircraft that typically seats 10-12 people, including the flight crew.

RUNWAY LENGTH RECOMMENDATIONS:

For airports with "B-II Small Aircraft" Critical Aircraft classifications, primary runway length recommendations by MDOT and FAA are as follows:

MDOT – *Source: Michigan Airport System Plan (MASP 2008):* **4,300 feet**
(statewide standard)

FAA – *Source: FAA Advisory Circular 150/5325-4B,* **4,200 feet** *
"Runway Length Requirements for Airport Design"
(airport-specific standard)

* *Note: The FAA runway length recommendation was obtained from Figure 2-2 in Advisory Circular 150/5325-4B. The following specifics for ARB were used in the determination: Airport Elevation: 839 feet above mean sea level*
Temperature: 83 degrees F mean daily maximum temp of hottest month of year (July)

RUNWAY LENGTH RECOMMENDATIONS (continued):

The FAA recommended runway length of 4,200 feet at ARB was obtained by calculation from FAA Advisory Circular 150/5325-4B, *"Runway Length Requirements for Airport Design"*, a publication that is used nationally by the agency. The resulting recommended runway lengths are airport-specific, and can vary by hundreds of feet from site to site, depending on the specific airport elevations and mean daily maximum temperatures used in the calculations.

The MDOT recommendation of 4,300 feet is a statewide standard for all airports in the state with B-II Small Critical Aircraft classifications. Since airport elevations and mean maximum temperatures do not vary significantly from airport to airport in Michigan, as opposed to many other states, MDOT uses a single runway length recommendation for all airports of the same Critical Aircraft classification. The FAA-Airports District Office that oversees the state of Michigan supports our statewide runway length recommendation of 4,300 feet for all airports classified with a B-II Small Aircraft reference code.

As stated in FAA Advisory Circular 150/5325-4B, "*The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions.*" Airplanes that are classified within an airport's Critical Aircraft category are considered by the FAA to be the "regular use" aircraft of the main primary runway.

Development of the primary runway at ARB to the recommended length of 4,300 feet would allow the majority of B-II Small classification aircraft to operate at their optimum capabilities (without weight restrictions). Interstate commerce into and out of a community can be negatively impacted if business aircraft are forced to operate with load restrictions (i.e. reductions in passengers, cargo, and fuel associated with aircraft range) due to lack of suitable runway length.

Extension of the runway to the recommended length would also enhance airport operational safety. A 4,300-foot long runway would not only provide enough runway for takeoff by most regular use (Critical Aircraft category) airplanes operating at optimum capabilities, but also provide additional runway for the purpose of bringing the aircraft to a stop in an aborted-takeoff situation. In situations where pilots detect a problem with the aircraft while on the takeoff roll, they are forced to continue the takeoff and contend with the problem in the air if there is not enough runway remaining to bring the aircraft to a stop. By having enough remaining runway to safely abort a takeoff and stop the aircraft while still on the ground, a pilot would be able to avoid a potentially hazardous situation of taking to the air with a mechanically-deficient aircraft.

CONCLUSION:

This user survey analysis has shown that justification of need for the proposed extension of Runway 6/24, based on a determination of the Critical Aircraft, has been substantiated according to MDOT and FAA standards. Even though records that were analyzed likely did not include all operations performed at ARB in 2007 by category B-II and greater aircraft, the operations that were substantiated with available information were more than sufficient to make the determination that the Critical Aircraft is of the "B-II Small Aircraft" classification. With this confirmation, we find the proposed project eligible to receive state and federal funding, and recommend that the airport sponsor proceed with the planning and environmental processes associated with the proposed extension of the primary runway to an overall length of 4,300 feet.

NOTE: *A Supplemental Report to this July 2009 Airport User Survey Report was issued in December 2009. The Supplemental Report provides additional details and updates to the information contained in this original report. The information published in the Supplemental Report provides additional justification to further support the findings and recommendations of this original July 2009 Airport User Survey Report.*

Appendix A-2. Supplemental Report
Airport User Survey
Ann Arbor Municipal Airport (ARB)
Ann Arbor, Michigan
December, 2009

SUPPLEMENTAL REPORT
AIRPORT USER SURVEY

ANN ARBOR MUNICIPAL AIRPORT (ARB)
ANN ARBOR, MICHIGAN

December 2009

This Supplemental Report is associated with the original Airport User Survey Report for Ann Arbor Municipal Airport (ARB), dated July 2009. The information contained in this supplement provides additional details and updates to the information contained in the original report.

Additional analysis of the aircraft operational data has resulted in the generation of supplemental information, three new exhibits, and updates to the numbers of annual operations performed by category B-II critical aircraft. The following paragraphs explain in detail the information provided in the new exhibits, as well as the supplemental information and updates to the operational numbers listed in the original user survey report.

EXHIBIT No. 1: *Annual Operations Analysis by Specific Aircraft Model*

This exhibit shows annual operations at ARB by specific aircraft model, rather than only by their FAA aircraft classification as shown in the original user survey report. The various aircraft models are listed in three separate tables, based upon groupings of their FAA classifications (B-II, C-I, and C-II).

Supplemental data associated with annual operations by the Beechcraft King Air C90 has been included in the B-II category table of this exhibit. Operations by this particular model of aircraft were not included in the original July 2009 Airport User Survey Report.

EXHIBIT No. 2: *Origin / Destination Analysis by State*

Exhibit No. 2 shows the results of an origin and destination analysis of aircraft operations conducted at ARB, based on examination of the FlightAware database from survey year 2007. Although 274 of the operations had aircraft model and ownership information blocked from the database at the aircraft owner's request, the origin and destination cities of each flight were still included.

The first column of the table shown in this exhibit lists 31 states (and Washington DC) from which operations into ARB originated, or operations out of ARB were going to as a destination. The second column lists operations attributed to each state by the 274 total operations with blocked aircraft and ownership records. The third and fourth columns list operations attributed to each state by B-II Small and B-II Large category aircraft. The last column lists the total number of operations attributed to each state.

The numbers of operations associated with each state are from the FlightAware Instrument Flight Rule (IFR) flight plan database only, and do not include records of all itinerant operations between ARB and other states. Nonetheless, the numbers shown in this exhibit confirm that in 2007, flight operations were conducted between ARB and at least 31 other states (approximately 63% of the continental US). Also, approximately 67% of the IFR flight records for the category B-II critical aircraft were between ARB and out-of-state locations. These factors confirm that there is a significant amount of flight operations being conducted at ARB that are either going to, or coming from, distant locations in other states.

<u>EXHIBIT No. 3</u>: ***Small 10-Seat Aircraft Analysis***

The table in this exhibit lists *Small* aircraft models (less than or equal to 12,500 lbs. maximum certificated takeoff weight) that have 10 or more passenger seats, and that conducted operations at ARB in survey year 2007. The numbers of annual operations listed in the table are from the FlightAware IFR flight plan database only, and do not include records of all operations by aircraft of this type. The FlightAware records show that there were 425 annual operations by Small 10-seat or higher aircraft.

Exhibit No. 3 also shows that there were 211 annual operations by *Large* category (greater than 12,500 lbs. maximum certificated takeoff weight) B-II aircraft from the Based Aircraft data source and another 85 annual operations by Large category B-II aircraft from the FlightAware data source. The number of annual operations performed by the Small 10-seat or higher aircraft and the Large category aircraft combined is shown as 721.

The operational numbers listed in Exhibit No. 3 do not include blocked FlightAware operations, Visual Flight Rule (VFR) operations, or operations logged by pilots on the Fixed Base Operator (FBO) airport registers. Although the information shown is only a partial representation of all applicable aircraft, the 721 annual operations that were substantiated significantly confirm that Figure 2-2 in FAA Advisory Circular 150/5325-4B is the appropriate chart to reference in the determination of the FAA-recommended runway length of 4,200 feet at ARB.

<u>UPDATED BASED AIRCRAFT ANALYSIS</u>:

The Based Aircraft Analysis of the original user survey report listed 200 estimated annual operations by AvFuel's B-II Large category aircraft (see page 3 of the original report). AvFuel's Chief Pilot has since confirmed in writing that the actual number of operations by their Cessna Citation XL 560 aircraft at ARB over the past three calendar years has been 224 operations in 2006, 211 operations in 2007, and 223 operations in 2008.

In order to maintain consistency with the other survey year 2007 operational records analyzed, Exhibit No. 1 of this Supplemental Report shows the 211 actual annual operations by this aircraft in the "Based Aircraft Data Source" column of the category B-II table, instead of the original estimate of 200.

<u>UPDATED ITINERANT AIRCRAFT ANALYSIS</u>: (FBO Data Sources)

Itinerant (visiting) aircraft operational data that was evaluated as part of the original user survey analysis was obtained from the pilot registration logs (airport registers) of two of the airport's FBOs - Solo Aviation and Ann Arbor Aviation Center. Data was examined for a six-month survey time frame, and cross-checked against FlightAware records in order to prevent counting the same aircraft twice. Any operations that were already included in the FlightAware records were not included in the operational totals that were generated from the FBO records.

The FBO records provided 40 additional operations by B-II and greater category aircraft (32 by category B-II aircraft, 6 by category C-I aircraft, and 2 by category C-II aircraft). Since this data was based on a six-month time frame instead of the full calendar year 2007, these 40 actual operations were prorated into an estimated equivalent annual rate of 80 operations. The additional 40 estimated operations were the only operations in the original user survey analysis that were obtained by prorating actual partial-year data into an estimated equivalent annual rate.

As part of the supplemental analysis, estimated operations that were originally generated as a result of prorating partial-year data were not considered in the determination of the annual operations at ARB. This eliminates the potential effect of seasonal variation in flight activity levels negatively influencing annual operational estimates. Only the 40 actual operations that were documented by the FBOs as having occurred within the six-month survey period were counted as valid operations, since they did in fact occur in 2007. No operations were attributed to the remaining six months.

Exhibit No. 1 of this supplemental report shows only the 40 actual documented operations (32 by category B-II aircraft, 6 by category C-I aircraft, and 2 by category C-II aircraft) in the column that is labeled "2 FBO Register Data Sources".

UPDATED FLIGHTAWARE DATABASE ANALYSIS:

The FlightAware database analysis that was performed for the original July 2009 Airport User Survey Report resulted in the determination of 265 actual annual operations by B-II Small aircraft, and another 85 actual annual operations by B-II Large aircraft (see page 6 of the original report). However, the resulting numbers did not include operations by the Beechcraft King Air C90 model.

The King Air C90 is a B-II Small category aircraft, with a wingspan of 50'3". Earlier versions of the King Air 90 models (A90 and B90) have wingspans of less than 49', and are therefore category B-I Small aircraft. Since the FlightAware records that were originally analyzed for ARB did not include information which identified the specific model of each King Air 90 operation, no operations by King Air 90s were included in the original user survey analysis and report.

Although the FlightAware records do not provide information regarding the specific model of each King Air 90 operation listed, they do provide the aircraft registration N-number of each aircraft. By entering the N-number into the computerized FAA aircraft registration database, the specific model of each King Air 90 operation was able to be determined. A total of 157 operations by the B-II Small category King Air C90 model have been identified, out of 220 operations by King Air 90 models of all types.

Exhibit No. 1 of this supplemental report shows the 157 King Air C90 operations included in the "Flight Aware Data Source" column of the category B-II table. By adding these operations to the 265 operations by B-II Small aircraft and 85 operations by B-II Large aircraft that were previously identified in the original user survey report, the updated total number of actual annual operations by B-II category aircraft obtained from the FlightAware data source is 507.

The FlightAware database also confirmed usage of the airport by many large corporations, in addition to AvFuel, which is the only one actually based at ARB. Some of the other corporate users of ARB include Synergy International, Wells Fargo, Polaris Industries, Bombardier Aerospace, Avis Industrial Corporation, Thumb Energy, and NetJets. NetJets provides on-demand air charter services and corporate aircraft fractional ownership opportunities to a large number of other corporations that are located throughout the country.

AIRCRAFT OPERATIONAL FORECASTS:

Year 2007 was the onset year of the current planning activities associated with the potential extension of Runway 6/24. At that time, the airport manager and FBOs were requested to collect based and itinerant aircraft operational data over the course of year 2007 for the purpose of determining project justification. This data was reviewed during the user survey analysis, which was conducted in early 2009.

FlightAware records for any given year are not published until that particular calendar year has ended, and all operations that took place during the course of that year counted. Since the user survey analysis was conducted in early 2009, the most current operational records available at the time from FlightAware were associated with calendar year 2008. Although year 2008 records were available, year 2007 records from FlightAware were used in the user survey analytical process. This was due to the importance of maintaining consistency of year of operational records in the analysis, and not combining operational data collected by the airport manager and FBOs over year 2007 with the more recent FlightAware records from year 2008. The FlightAware records, airport manager records, and FBO records from calendar year 2007 that were used in the user survey analysis were all only one-year old at the time, and still considered valid for use in determining project justification.

The FAA Terminal Area Forecast (TAF) does project a short-term approximate 22% decrease in total annual operations at ARB from user survey year 2007 through year 2009 (from 72,895 actual in 2007 to 56,956 estimated for 2009). However, beginning in year 2010, the TAF projects continuously increasing annual operations at ARB, from the year 2009 low-point through year 2030. Itinerant annual operations are even projected to surpass survey year 2007 levels prior to the end of the 2030 forecast period.

Even if the worst case short-term projected 22% decrease in total annual operations is applied to the user survey results, there is still significant justification for the runway extension. The user survey report documents a total of 750 actual annual operations by B-II category critical aircraft that justify the runway extension. A 22% decrease in this number is 585 - still well above the FAA's substantial use threshold of 500. And again, beginning in 2010, operations at ARB are projected by the FAA to begin increasing every single year from that point forward, through year 2030.

Forecasts from the MDOT Michigan Airport System Plan (MASP 2008) also project increasing itinerant and total operations at ARB from years 2010 through 2030. The MDOT forecasts further substantiate the mid-term and long-term FAA projections of a rebound in current operational activity at ARB to survey year 2007 levels.

AvFuel Corporation, which bases a B-II Large category Citation 560 Excel jet at ARB, has confirmed that their operations at ARB actually increased from 211 operations in 2007 to 223 operations in 2008. Their Chief Pilot estimates that their future operational levels could potentially increase to 350 to 450 operations per year at ARB.

The FAA TAF forecast, MDOT MASP forecast, and AvFuel's operational forecasts all provide support to the fact that survey year 2007 operational data is a very pertinent representation of estimated future operational levels at ARB.

SUMMARY:

The supplemental analysis that was conducted after publication of the July 2009 Airport User Survey Report has resulted in additional justification in support of extension of Runway 6/24 to 4,300' in length.

Further analysis of the FlightAware IFR flight plan database has confirmed 507 actual operations at ARB in survey year 2007 by B-II category aircraft. This number does not include operations in the FlightAware records with aircraft information blocked at the owner's request, or VFR operations that were conducted without flight plans. Judging by the high number of out-of-state origin and destination locations of operations listed in the blocked category (see Exhibit No. 2), it is very likely that many of the associated aircraft were of the B-II or greater categories. Therefore, actual operations at ARB by aircraft of these categories are likely considerably higher than the 507 substantiated operations obtained from the FlightAware database.

The 507 actual operations by B-II category aircraft that were obtained from the FlightAware database also do not include operations conducted by AvFuel's based Cessna Citation XL 560, or operations obtained from the two FBO airport registers. AvFuel has confirmed 211 actual operations at ARB in 2007 with their B-II category aircraft, and data provided by the FBOs has confirmed 32 actual operations in 2007 by B-II category aircraft.

In summary, the supplemental analysis of this user survey has confirmed a total of 750 actual annual operations at ARB by category B-II aircraft. FlightAware records also confirmed that operations by aircraft in this critical aircraft category were performed by many large corporations, some of which are listed on page 4 of this report.

CONCLUSION:

In the majority of airport user survey processes, determinations and recommendations are issued based on analysis of estimated annual operations obtained from various airport users. In conducting the user survey at ARB, the analysis focused on evaluation of actual annual operations performed at the airport. This is obviously a much more accurate method of calculating the total number of annual operations associated with the determination of the critical aircraft and Airport Reference Code. It also eliminates the possibility of an airport user inflating their estimated operational numbers, in the hopes of obtaining a longer runway that is not truly justified.

While the numbers listed in this report do not include every operation that occurred at ARB in survey year 2007 with B-II category aircraft, they do confirm substantial usage of the airport by aircraft of this critical aircraft category. The Origin/Destination Analysis has shown a significant number of operations between ARB and distant out-of-state locations, which is a very good indicator of corporate activity associated with interstate commerce, as opposed to pleasure flying by general aviation pilots. FlightAware records also confirmed usage of the airport by many large corporations.

The information contained in this Supplemental Report provides additional justification in support of the findings and recommendations of the original July 2009 Airport User Survey Report. The user survey analysis has shown that justification for the proposed extension of primary Runway 6/24 to 4,300-feet has been confirmed, and the proposed project has been determined to be eligible to receive state and federal funding.

Although justification for the proposed project has been substantiated according to current MDOT and FAA standards associated with runway length recommendations, neither agency requires that the runway be extended. It is ultimately – and entirely – the decision of the city of Ann Arbor whether or not to proceed with the development of the project.

ANN ARBOR MUNICIPAL AIRPORT USER SURVEY - SUPPLEMENTAL REPORT - DECEMBER 2009

EXHIBIT NO. 1

ANNUAL OPERATIONS ANALYSIS BY SPECIFIC AIRCRAFT MODEL

Aircraft Model	FAA Approach Category	FAA Design Group	FAA Weight Class	Seating	Maximum Takeoff Weight (lbs.)	Aircraft Engine Type	Flight-Aware Data Source	Based Aircraft Data Source	2 FBO Register Data Sources	Total Annual Operations by Model
Aero Commander 695	B	II	Small	<10	<12,500	Multi-Eng	4	0	0	4
Beechcraft King Air C90	B	II	Small	10+	<12,500	Multi-Eng	157	0	0	157
Beechcraft King Air 100	B	II	Small	10+	<12,500	Multi-Eng	39	0	2	41
Beechcraft King Air 200	B	II	Small	10+	<12,500	Multi-Eng	215	0	8	223
Cessna 441 Conquest II	B	II	Small	<10	<12,500	Multi-Eng	7	0	4	11
Beechcraft King Air 300	B	II	Large	10+	12,500+	Multi-Eng	11	0	8	19
Beechcraft King Air 350	B	II	Large	10+	12,500+	Multi-Eng	43	0	4	47
Cessna Citation II 550	B	II	Large	<10	12,500+	Jet	6	0	2	8
Cessna Citation XL 560	B	II	Large	<10	12,500+	Jet	25	211	2	238
Cessna Citation 680	B	II	Large	<10	12,500+	Jet	0	0	2	2
Total B-II Category Annual Operations							507	211	32	750

Learjet 25	C	I	Large	<10	12,500+	Jet	0	0	2	2
Learjet 31	C	I	Large	<10	12,500+	Jet	0	0	2	2
Learjet 45	C	I	Large	<10	12,500+	Jet	0	0	2	2
Total C-I Category Annual Operations							0	0	6	6

IAI Westwind 1125	C	II	Large	<10	12,500+	Jet	0	0	2	4
Total C-II Category Annual Operations							0	0	2	4

CRITICAL AIRCRAFT CATEGORY DETERMINATION: B-II (Based on 750 Total Annual Operations by Aircraft of this Category)

NOTE: The annual operations listed in the above tables are ACTUAL documented operations from calendar year 2007.
The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.
Operations recorded by the FBOs and listed above represent only a partial-year (six-month) time frame.

A total of 274 operations in the FlightAware database had aircraft model and ownership information blocked at the owner's request.
As a result, their operational numbers are NOT included in the information shown above.
Judging by the high number of out-of-state origin and destination locations of aircraft in the blocked category (see Exhibit No. 2), it is very likely that many of the associated aircraft were of the B-II and greater categories.
Therefore, actual operations at ARB by aircraft of these categories are likely considerably higher than the numbers shown above.

EXHIBIT NO. 2 **ORIGIN / DESTINATION ANALYSIS BY STATE**

Origin / Destination Analysis of IFR Aircraft Operations Between ARB and Other States
(Records from FlightAware 2007 Database)

	STATE	Aircraft Type & Category Blocked	B-II Small Category	B-II Large Category	Totals by State
1	Alabama	0	1	0	1
2	Arizona	1	0	0	1
3	Arkansas	2	1	0	3
4	Connecticut	5	2	0	7
5	Florida	29	3	3	35
6	Georgia	5	6	12	23
7	Illinois	25	64	5	94
8	Indiana	6	21	1	28
9	Iowa	1	20	3	24
10	Kansas	3	0	0	3
11	Kentucky	2	13	0	15
12	Maine	2	0	0	2
13	Maryland	1	3	7	11
14	Massachusetts	5	0	1	6
15	**Michigan**	**79**	**162**	**20**	**261**
16	Minnesota	2	3	2	7
17	Missouri	0	5	0	5
18	Nebraska	3	0	1	4
19	New Hampshire	1	2	0	3
20	New Jersey	9	2	4	15
21	New York	6	5	1	12
22	North Carolina	4	1	1	6
23	Ohio	16	38	13	67
24	Pennsylvania	14	23	4	41
25	South Carolina	0	4	0	4
26	South Dakota	4	18	0	22
27	Tennessee	2	5	0	7
28	Texas	30	0	0	30
29	Virginia	1	3	0	4
30	Washington DC	5	1	2	8
31	West Virginia	1	7	0	8
32	Wisconsin	10	9	4	23
	No Record	0	0	1	1
	Totals by Category	**274**	**422**	**85**	**781**

IFR Aircraft Operation Totals by Category:

Within Michigan	79	162	20	261
Outside of Michigan	195	260	64	519
No Record	0	0	1	1

NOTE: The numbers of operations listed above are ACTUAL documented operations from calendar year 2007. The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.

The numbers shown above are from the FlightAware IFR Flight Plan Database only, and do NOT include records of all itinerant operations between ARB and other states. Nonetheless, the numbers shown above confirm that in 2007, flight operations were conducted between ARB and at least 31 other states and Washington DC (approx 63% of the continental US). Approximately 67% of these IFR flight records were between ARB and out-of-state locations.

EXHIBIT NO. 3 **SMALL 10-SEAT AIRCRAFT ANALYSIS**

Small Airplanes Having 10 or More Passenger Seats (Records from FlightAware 2007 Database)							
Aircraft Model	**FAA Approach Category**	**FAA Design Group**	**FAA Weight Class**	**Seating**	**Maximum Takeoff Weight**	**Aircraft Engine Type**	**Annual Operations**
Cessna Caravan 208	A	II	Small	10+	<12,500	Single-Eng	11
Swearingen Merlin III	B	I	Small	10+	<12,500	Multi-Eng	3
Beechcraft King Air C90	B	II	Small	10+	<12,500	Multi-Eng	157
Beechcraft King Air 100	B	II	Small	10+	<12,500	Multi-Eng	39
Beechcraft King Air 200	B	II	Small	10+	<12,500	Multi-Eng	215

Total Small 10-Seat Aircraft Annual Operations **425**

Total B-II Large Category Aircraft Annual Operations

Based Aircraft Data Source (B-II Large):	**211**
FlightAware Data Source (B-II Large):	**85**

Grand Total Annual Operations at ARB Applicable to Figure 2-2 in FAA Advisory Circular 150/5325-4B: **721**

NOTE: The annual operations listed above are ACTUAL documented operations from canendar year 2007. The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.

The numbers shown in the table above are from the FlightAware IFR Flight Plan Database only, and do NOT include records of all small aircraft operations at ARB with 10-seat or greater aircraft models. Nonetheless, the above analysis confirms that Figure 2-2 in FAA AC 150/5325-4B is the appropriate chart to reference in the determination of the FAA-recommended runway length for Ann Arbor Municipal Airport.

Appendix B. Noise Analysis Report

(prepared by URS/July, 2009)

APPENDIX B-1

NOISE IMPACT ANALYSIS

B.1 AIRCRAFT NOISE

The compatibility of existing and planned land uses in the vicinity of an airport is usually associated with the extent of the airport's noise impacts. Airport development actions to accommodate fleet mix changes, the number of aircraft operations, or air traffic changes are examples of activities that can alter aviation-related noise impacts and affected land uses subjected to those impacts. This section describes the baseline noise environment and the associated land use compatibility.

B.1.1 APPLICABLE REGULATIONS

The evaluation of the Ann Arbor Municipal Airport (ARB) noise environment, and land use compatibility associated with airport noise, was conducted using the methodologies developed by the Federal Aviation Administration (FAA) and published in FAA Order 5050.4B, FAA Order 1050.1E, and title 14 Code of Federal Regulations (CFR) part 150.

For aviation noise analysis, the FAA has determined that the cumulative noise energy exposure of individuals to noise resulting from aviation activities must be established in terms of yearly day/night average sound level (DNL); this is FAA's primary metric. Title 14 CFR part 150 provides Federal compatible land use guidelines for several land uses as a function of DNL values. The ranges of DNL values in Table B-1 reflect the statistical variability for the responses of large groups of people to noise. Compatible or non-compatible land use is determined by comparing the predicted or measured DNL values at a site to the values listed in Table B-1. Land use compatibility with yearly day-night average sound levels is shown in Table B-1.

B.1.2 METHODOLOGY

Aircraft Noise Descriptors and Effects
The terms and metrics associated with aircraft noise relative to this analysis are complex and are discussed in detail in Appendix B-2 along with potential effects of aircraft noise. In general and in this document, noise or sound levels are expressed in terms of A-weighted decibels (dBA).

DNL is a 24-hour time-weighted-average noise metric expressed in dBA which accounts for the noise levels of all individual aircraft events, the number of times those events occur, and the time of day which they occur. DNL has two time periods: daytime (7:00 a.m. to 9:59 p.m.) and nighttime (10:00 p.m. to 6:59 a.m.). In order to represent the added intrusiveness of sounds occurring during nighttime hours, DNL penalizes, or weights, events occurring during the nighttime periods by 10 dBA.

Noise and Compatible Land Use Prediction Methodology
The Integrated Noise Model (INM) has been FAA's standard tool since 1978 for determining the predicted noise impact in the vicinity of airports. Statutory requirements for INM use are defined in FAA Order 1050.1E, *Environmental Impacts: Policies and Procedures*; Order 5050.4B, *National Environmental Policy Act (NEPA) Implementing Instructions for Airport Actions*; and title 14 CFR part 150, *Airport Noise Compatibility Planning*. INM Version 7.0a, released September 17, 2008, was the version used for this document (http://www.faa.gov/about/office_org/headquarters_offices/aep/models/ inm_model/).

The INM incorporates the number of annual average daily daytime and nighttime flight and run-up operations, flight paths, run-up locations, and flight profiles of the aircraft along with its extensive internal database of aircraft noise and performance information, to calculate the DNL at many points on the ground around an airport. From a grid of points, the INM contouring program draws contours of equal DNL to be superimposed onto land use maps. For this document, DNL contours of 65, 70, and 75 dBA were developed. DNL contours are a graphical representation of how the noise from the airport's average annual daily aircraft operations is distributed over the surrounding area. The INM can calculate sound levels at any specified point so that noise exposure at representative locations around an airport can be obtained.

TABLE B-1
LAND USE COMPATIBILITY WITH YEARLY DAY-NIGHT AVERAGE SOUND LEVELS

	Yearly Day-Night Average Sound Level (DNL)					
	Below 65 Decibels	65-70 Decibels	70-75 Decibels	75-80 Decibels	80-85 Decibels	Over 85 Decibels

NOTE: The responsibility for determining the acceptable and permissible land uses and the relationship between specific properties remains with the local authorities. FAA determinations under Part 150 are not intended to substitute Federally determined land use for those determined to be appropriate by local authorities in response to locally determined needs and values in achieving noise-compatible land uses.

KEY TO TABLE:

SLUCM	Standard Land Use Coding Manual.
Y (Yes)	Land Use and related structures are compatible without restrictions.
N (No)	Land Use and related structures are not compatible and should be prohibited.
NLR	Noise Level Reduction (outdoor to indoor) are to be achieved through incorporation of noise attenuation into the design and construction of structure.
25,30, or 35	Land use and related structures are generally compatible; measures to achieve NLR of 25, 30, or 35 dB must be incorporated in design and construction of structure.

[1] Where the community determines that residential or school uses must be allowed, measures to achieve outdoor to indoor NLR of at least 25 dB and 30 dB should be incorporated into building codes and be considered in individual approvals. Normal residential construction can be expected to provide a NLR of 20 dB, thus, the reduction requirements are often stated as 5, 10 or 15 dB over standard construction and normally assume mechanical ventilation and closed windows year round. However, the use of NLR criteria will not eliminate outdoor noise problems

[2] Measures to achieve NLR of 25 dB must be incorporated into the design and construction of portions of the buildings where the public is received, office areas, noise-sensitive areas, or where the normal noise level is low.

[3] Measures to achieve NLR of 30 dB must be incorporated into the design and construction of portions of the buildings where the public is received, office areas, noise-sensitive areas, or where the normal noise level is low.

[4] Measures to achieve NLR of 35 dB must be incorporated into the design and construction of portions of the buildings where the public is received, office areas, noise-sensitive areas, or where the normal noise level is low.

[5] Land use compatible provided special sound reinforcement systems are installed.

[6] Residential buildings require an NLR of 25 dB.

[7] Residential buildings require an NLR of 30 dB.

[8] Residential buildings not permitted.

Noncompatible land use.

Source: Title 14 CFR part 150, Appendix A, Table 1, January 1998.

The INM is an average-value-model and is designed to estimate long-term average effects using average annual input conditions. Because of this, differences between predicated and measured values can occur because certain local acoustical variables are not averaged, or because they may not be explicitly modeled in INM. Difference may also occur due to errors or improper procedures employed during the collection of the measured data.

Examples of detailed local acoustical variables include:

- Temperature profiles;
- Wind gradients;
- Humidity effects;
- Ground absorption;
- Individual aircraft directivity patterns; and
- Sound diffraction caused by water, buildings, barriers, etc.

The results of the INM analysis provide a relative measure of noise levels around airfield facilities. When the calculations are made in a consistent manner, the INM is most accurate for comparing before and after noise effects resulting from forecast changes or alternative noise control actions. It allows noise levels to be predicted for such proposed projects without the actual implementation and noise monitoring of those actions.

B.1.3 DATA

Sources
Data was collected from multiple sources, examined, and utilized to ensure that this aircraft noise analysis provides an accurate depiction of the existing ARB aircraft noise environment. The data sources utilized for this analysis included:

- Flight Explorer®, computer software which obtains N-number (registration number), aircraft type, arrival and departure airport, and time of day from Air Traffic Control Tower radar data,
- USDOT, FAA Airport Master Record, Form 5010 July 2009;
- FAA Terminal Area Forecast (TAF) December 2008;
- FAA Air Traffic Activity Data System (ATADS) May 2009;
- Michigan Department of Transportation (MDOT) Airport User Survey Report 2009;
- National Oceanic and Atmospheric Administration, Climatography of the United States No. 81, 2002; and
- Ann Arbor Municipal Airport, Airport Layout Plan.

Modeled Aircraft Operations
This section describes the sources and derivation of the INM input data for the existing conditions, which are based on aircraft operations occurring from April 2008 through March 2009, and 2014 future conditions. Items also discussed includes the airport layout, weather, flight operations, fleet mix, runway use, flight tracks, and track use.

Airport Layout
ARB has a single paved runway, which is designated as Runway 06/24. It is 3,505 feet long by 75 feet wide. A full parallel taxiway system, 30 feet wide, supports this runway. The Proposed Project consists of extending Runway 06/24 795 feet to a length of 4,300 feet. There is a secondary turf runway, designated Runway 12/30. Runway 12/30 is 2,750 feet long by 110 feet wide with a 25 foot wide full length turf taxiway. The field elevation at ARB is approximately 829 feet above sea level. Apron and hangar facilities are available for based and transient aircraft.

Weather and Climate
The INM default for pressure, humidity, and headwind was not changed in the model. INM uses temperature, pressure, and headwind when computing procedural profiles. Humidity is only used in calculating atmospheric absorption. The average temperature at Ann Arbor, the University of Michigan, the closest monitoring station, is 49 degrees Fahrenheit (NOAA Climatography of the United States No. 81, 2002). The INM default airport pressure is 29.92 inches of mercury and the default humidity is 70% and the default average headwind is 8 knots.

Flight Operations
INM-modeled annual operations for the 2009 existing condition, consisting of operations from April 2008 through March 2009, totaled 61,969 operations, which is approximately 169 daily operations. Jet operations accounted for approximately 2 percent of the total operations. Nighttime operations accounted for 4.2 percent of the total operations. The total number of operations were obtained from the FAA's ATADS. Air taxi / commuter operations fleet mix was obtained from Flight Explorer® data and general aviation aircraft fleet mix was obtained from the MDOT Airport User's Survey.

2014 future condition aircraft operations were obtained from the 2008 FAA TAF for ARB. Modeled annual operations for the 2014 condition totaled 69,717 operations, or approximately 191 daily operations. It is assumed that the percent of night and jet operations will remain constant between the existing condition and the future years. In addition, it is also assumed that the fleet mix between the 2009 Existing Condition and the 2014 Future Alternatives will remain static. The existing and future fleet mix with annual operations is shown in Table B-2.

Runway Use
Runway use at ARB was determined through discussions with the Air Traffic Control Tower (ATCT) staff. Runway utilization is approximately 30/70 percent on Runway 06/24, respectively. Discussions with ATCT staff also indicate that approximately 5 percent of single engine piston aircraft operations occur on Runway 12/30 with a 50/50 split. Helicopters operate to and from the east edge of the terminal apron. Table B-3 provides runway utilization by aircraft category. The 2014 No Action and Proposed Project Alternatives will maintain the same runway utilization.

Table B-3
Runway Utilization
Ann Arbor Municipal Airport
Runway Extension EA

Aircraft Type	Runway Utilization[1]			
	06	24	12	30
Jet	30 %	70 %	---	---
Turboprop	30 %	70 %	---	---
Multi-Engine Piston	30 %	70 %	---	---
Single Engine Piston	27.5 %	67.5 %	2.5 %	2.5 %

Source: ARB Air Traffic Control Tower
Note: 1. Utilization applies to arrival, departure, and touch-and-go operations.

Flight Tracks and Utilization
Flight tracks are the aircraft's actual path through the air projected vertically onto the ground. Due to the level of operations occurring at ARB, a single arrival and departure track for each runway end was appropriate for the noise modeling. Straight out departures tracks were modeled for all runways. Straight in arrivals to Runway 12/30 were modeled and arrivals to Runway 6/24 followed the published VOR procedures.

Unique helicopter and touch-and-go flight tracks were also modeled based on ATCT interviews. 80 percent of the helicopter operations arrive from or depart to the north, with the remaining 20 percent distributed evenly between arrivals from and departures to the east, south, and west.

B.1.4 IMPACT ANALYSIS

Existing Conditions
Noise exposure resulting from aircraft operations in 2009 at ARB is depicted as DNL 65, 70, and 75 dBA contours, superimposed over the local aerial map of Ann Arbor, on Figure 4-1. The ARB 2009 existing condition DNL 65 dBA noise contour does not extend beyond airport property.

No Action Alternative
Noise exposure resulting from aircraft operations for the 2014 No Action Alternative ARB is depicted as DNL 65, 70, and 75 dBA contours, superimposed over the local aerial map of Ann Arbor, on Figure 4-2. The ARB 2014 No Action Alternative DNL 65 dBA noise contour does not extend beyond airport property.

Proposed Project
Noise exposure resulting from aircraft operations for the 2014 Proposed Project Alternative at ARB is depicted as DNL 65, 70, and 75 dBA contours, superimposed over the local aerial map of Ann Arbor, on Figure 4-3. The ARB 2014 Proposed Project Alternative DNL 65 dBA noise contour does not extend beyond airport property.

APPENDIX B-2

AIRCRAFT NOISE, NOISE METRICS & THE INTEGRATED NOISE MODEL

Appendix B-2 describes the various common noise metrics and human perceptions. It also describes the Integrated Noise Model (INM), and its required inputs.

THIS PAGE INTENTIONALLY LEFT BLANK

APPENDIX B-2

AIRCRAFT NOISE, NOISE METRICS & THE INTEGRATED NOISE MODEL

1.1 AIRCRAFT NOISE

Aircraft noise originates from the engines as well as the airframe or structure of aircraft. The engines are generally the most significant source of noise. While noise generated by propeller-driven aircraft can be annoying, jet aircraft are commonly the source of disturbing noise at airports. Two basic types of jet aircraft are operated today equipped with turbofan or turbojet engines. Aircraft flying faster than the speed of sound generate an intense pressure wave called a sonic boom, in addition to the propulsion and airframe noise.

Turbofan engines produce thrust as reaction to the rate at which high-velocity gas is exhausted from nozzles. The engine core consists of a compressor, combustion chambers, a turbine and a front fan. The major sources of noise include the core engine fan streams, the compressor, turbine blades and exhaust nozzles. In comparison, turbojet aircraft do not have the front fan component. It has been found in several cases that the sound energy produced by a turbojet engine is greater than that of a turbofan engine with an equivalent thrust rating.

The noise produced by jet aircraft flyovers is characterized by an increase in sound energy as the aircraft approaches, up to a maximum level. This sound level begins to lessen as the aircraft passes overhead and then decreases in a series of lesser peaks as the aircraft departs the area.

Noise produced by propeller driven aircraft and helicopters emanates from the blades and rotors. There are two components of this noise, namely vortex and periodic. Vortex noise is generated by the formation and shedding of vortices in the airflow past the blade. Periodic noise is produced by the oscillating pressure field in the air that results from the passage of air past the blade. Blade slap is an additional source of noise in helicopters. This is high-amplitude periodic noise and highly modulated vortex noise caused by fluctuating forces as one blade cuts through the tip vortices of another.

1.2 AIRCRAFT NOISE TERMINOLOGY

The Federal Aviation Administration (FAA) uses a variety of noise metrics to assess potential airport noise impacts. Different noise metrics can be used to describe individual noise events (e.g., a single operation of an aircraft taking off overhead) or groups of events (e.g., the cumulative effect of numerous aircraft operations, the collection of which creates a general noise environment or overall exposure level). Both types of descriptors are helpful in explaining how people tend to respond to a given noise condition. Descriptions of the metrics used in this Part 150 Study are provided in the following text.

Decibel, dB – Sound is a complex physical phenomenon consisting of many minute vibrations traveling through a medium, such as air. The human ear senses these vibrations as sound pressure. Because of the vast range of sound pressure or intensity detectable by the human ear, sound pressure level (SPL) is represented on a logarithmic scale known as decibels (dB). A SPL of 0 dB is approximately the threshold of human hearing and is barely audible under extremely quiet (laboratory-type) listening conditions. A person begins to feel a SPL of 120 dB inside the ear as discomfort, and pain begins at approximately 140 dB. Most environmental sounds have SPLs ranging from 30 to 100 dB.

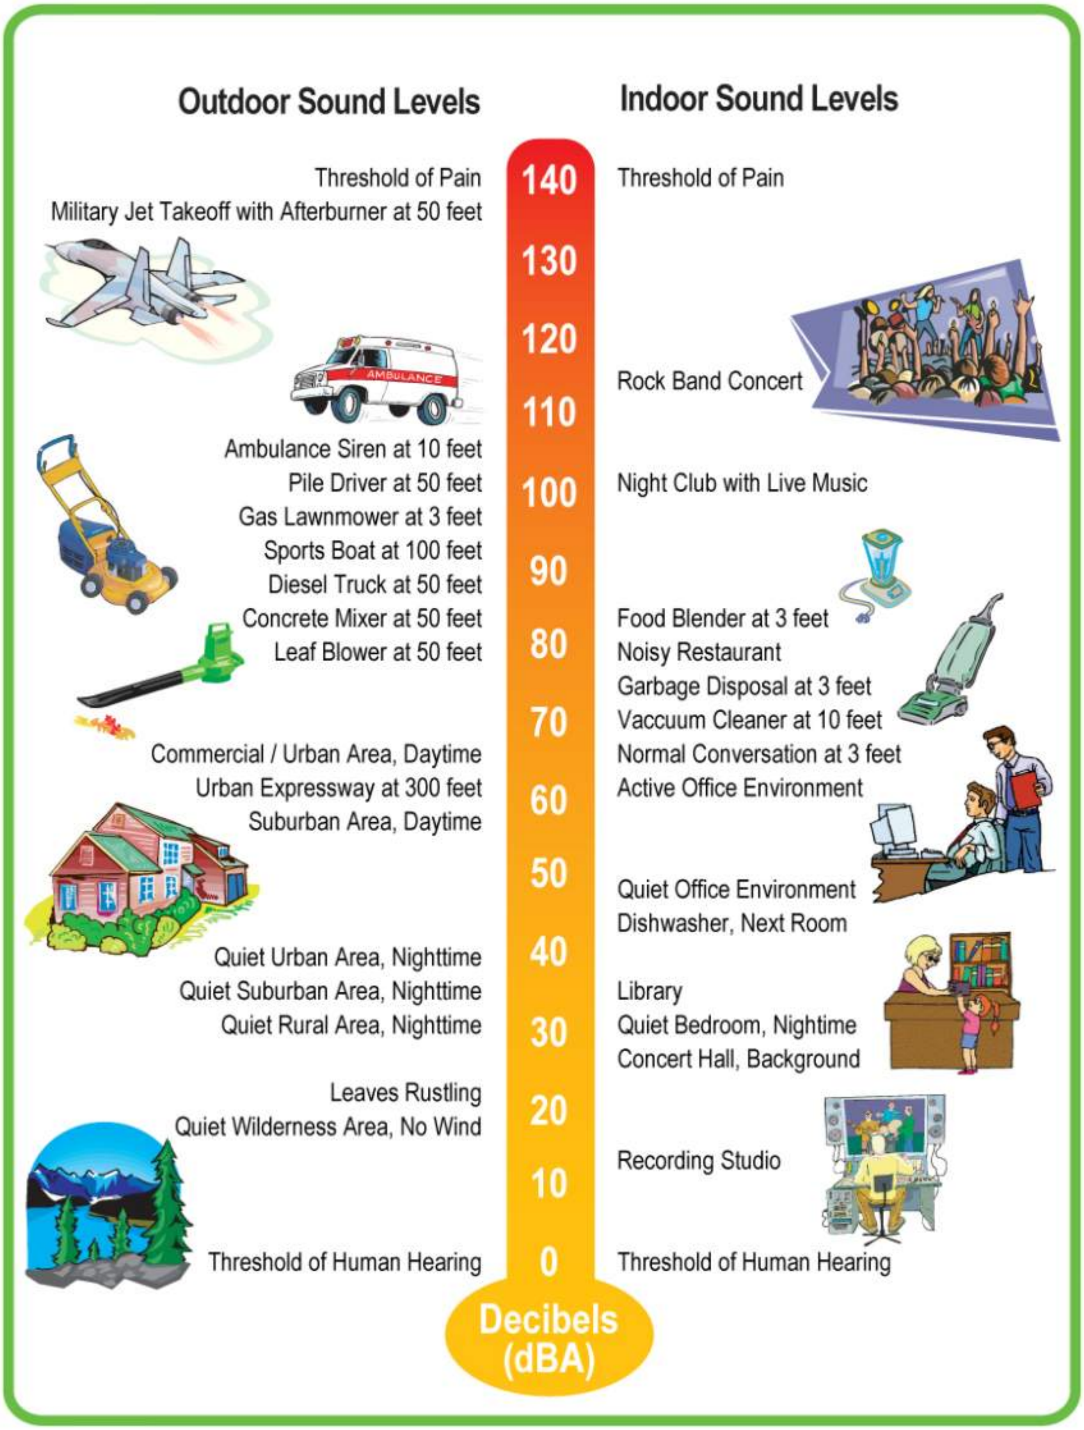
Because decibels are logarithmic, they cannot be added or subtracted directly like other (linear) numbers. For example, if two sound sources each produce 100 dB, when they are operated together they will produce 103 dB, not 200 dB. Four 100 dB sources operating together again double the sound energy, resulting in a total SPL of 106 dB, and so on. In addition, if one source is much louder than another, the two sources operating together will produce the same SPL as if the louder source were operating alone. For example, a 100 dB source plus an 80 dB source produces 100 dB when operating together. The louder source masks the quieter one.

Two useful rules to remember when comparing SPLs are: (1) most people perceive a 6 to 10 dB increase in SPL between two noise events to be about a doubling of loudness, and (2) changes in SPL of less than about 3 dB between two events are not easily detected outside of a laboratory.

A-Weighted Decibel, dBA – Frequency, or pitch, is a basic physical characteristic of sound and is expressed in units of cycles per second or hertz (Hz). The normal frequency range of hearing for most people extends from about 20 to 15,000 Hz. Because the human ear is more sensitive to middle and high frequencies (i.e., 1000 to 4000 Hz), a frequency weighting called “A” weighting is applied to the measurement of sound. The internationally standardized "A" filter approximates the sensitivity of the human ear and helps in assessing the perceived loudness of various sounds. For this Part 150 Study, all sound levels are A-weighted sound levels and the text typically omits the adjective "A-weighted".

Figure 1 charts common indoor and outdoor sound levels. A quiet rural area at nighttime may be 30 dBA or lower, while the operator of a typical gas lawn mower may experience a level of 90 dBA. Similarly, the level in a library may be 30 dBA or lower, while the listener at a rock band concert may experience levels near 110 dBA.

FIGURE 1
COMMON OUTDOOR AND INDOOR SOUND LEVELS



Source: URS Corp, 2008.

Maximum A-Weighted Noise Level, L_{max} – Sound levels vary with time. For example, the sound increases as an aircraft approaches, then falls and blends into the ambient, or background, as the aircraft recedes into the distance. Because of this variation, it is often convenient to describe a particular noise "event" by its highest or maximum sound level (L_{max}). It should be noted that L_{max} describes only one dimension of an event; it provides no information on the cumulative noise exposure generated by a sound source. In fact, two events with identical L_{max} levels may produce very different total noise exposures. One may be of very short duration, while the other may last much longer.

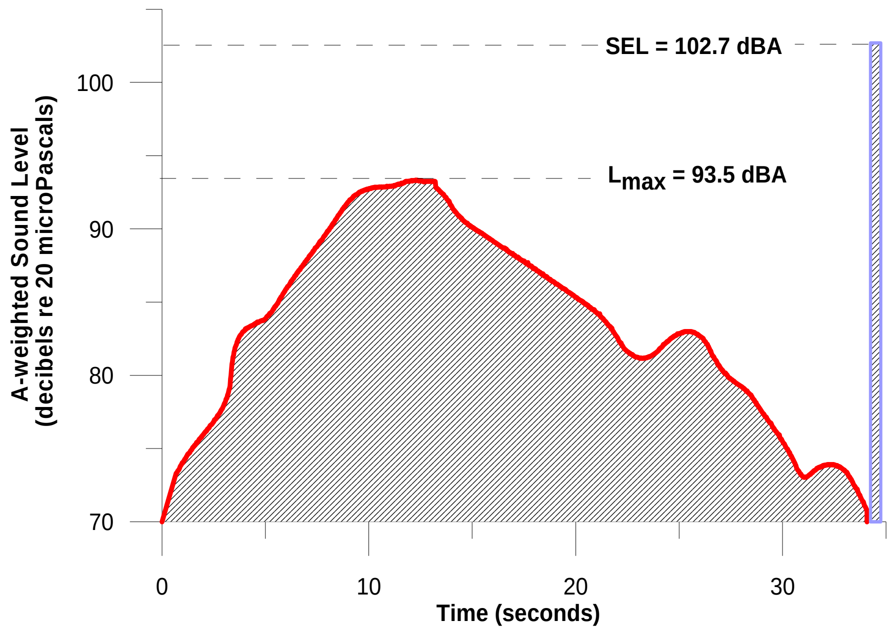
Sound Exposure Level, SEL – The most common measure of noise exposure for a single aircraft flyover event is the SEL. SEL is a summation of the A-weighted sound energy at a particular location over the true duration of a noise event, normalized to a fictional duration of one second. The true noise event duration is defined as the amount of time the noise event exceeds a specified level (that is at least 10 dB below the maximum value measured during the noise event). For noise events lasting more than one second, SEL does not directly represent the sound level heard at any given time, but rather provides a measure of the net impact of the entire acoustic event.

The normalization to the fictional duration of one second enables the comparison of noise events with differing true duration and/or maximum level. Because the SEL is normalized to one second, it will almost always be larger in magnitude than the L_{max} for the event. In fact, for most aircraft events, the SEL is about 7 to 12 dB higher than the L_{max}. Additionally, since it is a cumulative measure, a higher SEL can result from either a louder or longer event, or a combination thereof.

Since SEL combines an event's overall sound level along with its duration, SEL provides a comprehensive way to describe noise events for use in modeling and comparing noise environments. Computer noise models, such as the Integrated Noise Model (INM) that the FAA used for this PART 150 STUDY, base their computations on these SELs.

Figure 2 shows an event's "time history", or the variation of sound level with time. For typical sound events experienced by a stationary listener, like a person experiencing an aircraft flyover, the sound level rises as the source (or aircraft) approaches the listener, peaks and then diminishes as the aircraft flies away from the listener. The area under the time history curve represents the overall sound energy of the noise event. The L_{max} for the event shown in **Figure 2** was 93.5 dBA. Compressing the event's total sound energy into one second yields an SEL of 102.7 dBA.

FIGURE 2
COMPARISON OF MAXIMUM SOUND LEVEL (L_{MAX}) AND SOUND EXPOSURE LEVEL (SEL)



Source: URS Corporation, 2008.

<u>Equivalent Sound Level, L_{eq}</u> – Equivalent sound level (L_{eq}) is a measure of the noise exposure resulting from the accumulation of A-weighted sound levels over a particular period of interest (e.g., an hour, an 8-hour school day, nighttime, or a full 24-hour day). However, because the length of the period can be different depending on the period of interest, the applicable period should always be identified or clearly understood when discussing this metric. Such durations are often identified through a subscript. For example, for an 8 hour or 24 hour day, $L_{eq(8)}$ or $L_{eq(24)}$ is used, respectively.

Conceptually, L_{eq} may be thought of as a constant sound level over the period of interest that contains as much sound energy as the actual time-varying sound level with its normal "peaks" and "dips". In the context of noise from typical aircraft flight events, and as noted earlier for SEL, L_{eq} does not represent the sound level heard at any particular time, but rather represents the total sound exposure for the period of interest. Also, it should be noted that the "average" sound level suggested by L_{eq} is not an arithmetic value, but a logarithmic, or "energy-averaged," sound level. Thus, loud events tend to dominate the noise environment described by the L_{eq} metric.

<u>Day-Night Average Sound Level, DNL</u> – Time-average sound levels are measurements of sound averaged over a specified length of time. These levels provide a measure of the average sound energy during the measurement period. For the evaluation of community noise effects, and particularly aircraft noise effects, the Day-Night Average Sound Level (abbreviated DNL) is used. DNL logarithmically averages aircraft sound levels at a location over a complete 24-hour period, with a 10-decibel adjustment added to those noise events occurring between 10:00 p.m. and 7:00 a.m. (local time) the following morning. The FAA defines the 10:00 p.m. to 7:00 a.m. period as nighttime (or night) and the 7:00 a.m. to 10:00 p.m. period as daytime (or day). Because of the increased sensitivity to noise during normal sleeping hours and because ambient (without aircraft) sound levels during nighttime are typically about 10 dB lower than during daytime hours, the 10-decibel adjustment, or "penalty," represents the added intrusiveness of sounds occurring during nighttime hours.

DNL accounts for the noise levels (in terms of SEL) of all individual aircraft events, the number of times those events occur and the period of day/night in which they occur. Values of DNL can be measured with standard monitoring equipment or predicted with computer models such as the INM.

Typical DNL values for a variety of noise environments are shown in **Figure 3**. DNL values can be approximately 85 dBA outdoors under an aircraft flight path within a mile of a major airport and 40 dBA or less outdoors in a rural residential area.

Due to the DNL descriptor's close correlation with the degree of community annoyance from aircraft noise, most federal agencies have formally adopted DNL for measuring and evaluating aircraft noise for land use planning and noise impact assessment. Federal committees such as the Federal Interagency Committee on Urban Noise (FICUN) and the Federal Interagency Committee on Noise (FICON), which include the Environmental Protection Agency (EPA), the FAA, Department of Defense, Department of Housing and Urban Development, and the Veterans Administration, found DNL to be the best metric for land use planning. They also found no new cumulative sound descriptors or metrics of sufficient scientific standing to substitute for DNL. Other cumulative metrics are used only to supplement, not replace, DNL. Furthermore, FAA Order 1050.1E, *Policies and Procedures for Considering Environmental Impacts*, requires DNL be used in describing cumulative noise exposure and in identifying aircraft noise/land use compatibility issues (EPA, 1974; FICUN, 1980; FICON, 1992; title 14 CFR part 150, 2004; FAA, 2006).

The accuracy and validity of DNL calculations depend on the basic information used in the calculations. At airports, the reliability of DNL calculations is affected by a number of uncertainties:

- The noise descriptions used in the DNL procedure represent the typical human response to aircraft noise. Since people vary in their response to noise and because the physical measure of noise accounts for only a portion of an individual's reaction to that noise, the DNL scale can show only an average response to aircraft noise that may be expected from a community.
- Future aviation activity levels such as the forecast number of operations, the operational fleet mix, the times of operation (day versus night) and flight tracks are estimates. Achievement of forecasted levels of activity cannot be assured.
- Aircraft acoustical and performance characteristics for new aircraft designs are estimates.

<u>Outdoor vs. Indoor Noise Levels</u> – INM calculates outdoor noise levels, while some of the supplemental noise analysis effects are based on noise levels experienced indoors. In order to convert outdoor noise levels to indoor noise levels, an Outdoor-to-Indoor Noise Level Reduction (OILR) is identified. The indoor noise level is equal to the outdoor noise level minus the OILR. Based on accepted research, typical OILR values range between 15 dBA to 25 dBA, depending on the structure and whether windows are open or closed (Wyle, 1989).

1.3 EFFECTS OF AIRCRAFT NOISE ON PEOPLE

The most common effects regarding aircraft noise are related to annoyance and activity interference (e.g., speech disruption and sleep interference). These effects have been studied extensively and relationships between various noise metrics and effects have been established. The following sections summarize these effects, and the noise metrics that are used to describe them.

1.3.1 Speech Interference

Speech interference is the most readily quantified adverse effect of noise, and speech is the activity most often affected by environmental noise. The levels of noise that interfere with listening to a desired sound, such as speech, music, or television, can be defined in terms of the level of noise required to mask the desired sound. Such levels have been quantified for speech communications by directly measuring the interference with speech. Several studies have been conducted over the last 30 years resulting in various noise level criteria for speech interference.

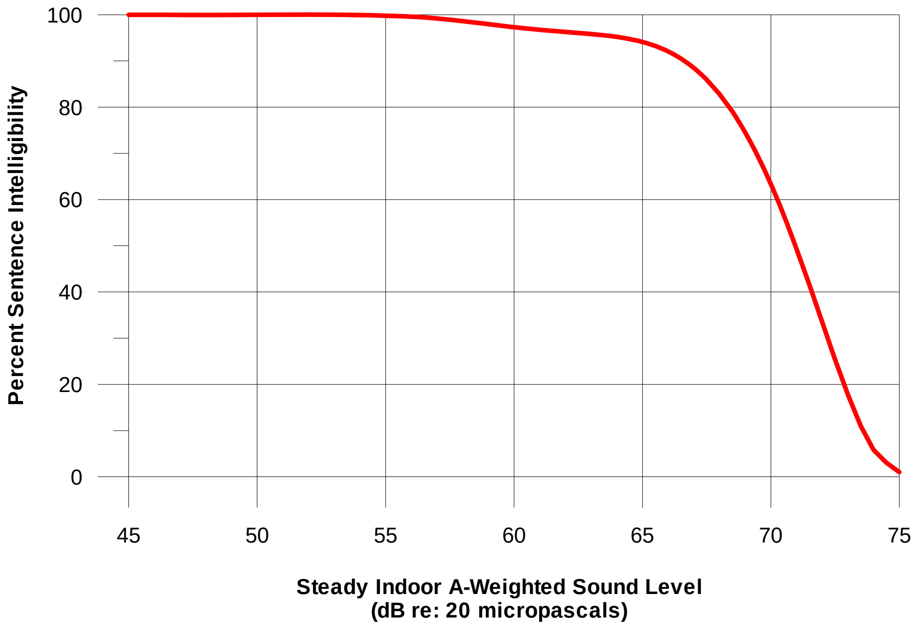
As an aircraft approaches and its sound level increases, speech becomes harder to hear. As the ambient level increases, the speaker must raise his/her voice, or the individuals must get closer together to continue talking. For typical communication distances of 3 or 4 feet (1 to 1.5 meters), acceptable outdoor conversations can be carried on in a normal voice as long as the ambient noise outdoors is less than about 65 dBA (FICON, 1992). If the noise exceeds this level, intelligibility would be lost unless vocal effort was increased or communication distance was decreased.

Indoor speech interference can be expressed as a percentage of sentence intelligibility between two average adults with normal hearing, speaking fluently in relaxed conversation approximately one meter apart in a typical living room or bedroom (EPA, 1974). Intelligibility pertains to the percentage of speech units correctly understood out of those transmitted, and specifies the type of speech material used, i.e. sentence or word intelligibility (ANSI, 1994). As shown in Figure 4, the percentage of sentence intelligibility is a non-linear function of the (steady) indoor ambient or background sound level (energy-average equivalent sound level (L_{eq})). For an average adult with normal hearing and fluency in the language, steady ambient indoor sound levels of up to 45 dBA L_{eq} are expected to allow 100 percent intelligibility of sentences. The curve shows 99 percent sentence intelligibility for L_{eq} at or below 54 dBA and less than 10 percent intelligibility for L_{eq} greater than 73 dBA. It should be noted that the function is especially sensitive to changes in sound level between 65 dBA and 75 dBA. As an example of the sensitivity, a 1 dBA increase in background sound level from 70 dBA to 71 dBA results in a 14 percent decrease in sentence intelligibility. In contrast, a 1 dBA increase in background sound level from 60 dBA to 61 dBA results in less than 1 percent decrease in sentence intelligibility.

The noise from aircraft events is not continuous, but consists of individual events where the noise level can greatly exceed the background level for a limited period as the aircraft flies over. Since speech interference in the presence of aircraft noise is essentially determined by the magnitude and frequency of individual aircraft flyover events, a time-averaged metric (such as L_{eq}) alone, is not necessarily appropriate when setting standards regarding acceptable levels. In addition to the background levels described above, single event criteria, which account for those sporadic intermittent noisy events, are also essential to specifying speech interference criteria. In order for two people to communicate reasonably using normal voice levels indoors, the background noise level should not exceed 60 dBA

(EPA, 1974). In other words, an indoor noise event that exceeds 60 dBA has the potential to cause speech and communication disruption (Eagan, 2007).

Figure 4
PERCENT SENTENCE INTELLIGIBILITY FOR INDOOR SPEECH



Source: U.S. Environmental Protection Agency, 1974.

1.3.2 Effect on Children's Learning

An important application of speech interference criteria is in the classroom where the percent of words (rather than whole sentences) transmitted and received, commonly referred to as 'word intelligibility,' is critical. For teachers to be clearly understood by their students, it is important that regular voice communication is clear and uninterrupted. Not only does the steady background sound level have to be low enough for the teacher to be clearly heard, but intermittent outdoor noise events also need to be unobtrusive. The steady ambient level, the level of voice communication, and the single event level (e.g., aircraft over-flights) that might interfere with speech in the classroom are measures that can be evaluated to quantify the potential for speech interference in the classroom.

Accounting for the typically intermittent nature of aircraft noise where speech is impaired only for the short time when the aircraft noise is close to its maximum value, different researchers and regulatory organizations have recommended maximum allowable indoor noise levels ranging between 40 and 60 dBA L_{max}. (Lind, et. al., 1998; Sharp and Plotkin, 1984; Wesler, 1986; WHO, 1999; ASLHA, 1995; ANSI, 2002). A single event noise level of 50 dBA L_{max} correlates to 90 percent of the words being understood by students with normal hearing and no special needs seated throughout a classroom (Lind, et. al., 1998). At-risk students may be adversely affected at lower sound levels.

ANSI has developed a standard for classrooms that states that the sound level during the noisiest hour should not exceed a one-hour average L_{eq} of 40 dBA for schools exposed to intermittent noise sources such as aircraft noise (ANSI, 2002). The standard further states that the hourly L_{eq} should not be exceeded for more than 10 percent of the noisiest hour (i.e., L_{eq} should not exceed L_{10}). FAA Order 5100.38C, Airport Improvement Program Handbook, Chapter 7, Section 2, Paragraph 812c(1) indicates that schools should have an A-weighted L_{eq} of 45 dB, or less, during school hours, in the classroom environment. Facilities not typically disrupted by aircraft, such as gymnasiums, cafeterias, or hallways, are not usually eligible for noise insulation. However, ANSI recommends that schools have a maximum one-hour average A-weighted unsteady background noise level of L_{eq} of 40 dB, or less, during school hours. Ancillary spaces, such as gymnasiums and cafeterias are recommended to have a maximum L_{eq} of 45 dB.

1.3.3 Sleep Disturbance

The EPA identified an indoor DNL of 45 dB as necessary to protect against sleep interference (EPA, 1974). Prior to and after the EPA's 1974 guidelines, research on sleep disruption from noise has led to widely varying observations. In part, this is because: (1) sleep can be disturbed without causing awakening, (2) the deeper the sleep the more noise it takes to cause arousal, (3) the tendency to awaken increases with age, and (4) the person's previous exposure to the intruding noise and other physiological, psychological, and situational factors. The most readily measurable effect of noise on a sleeping person is the number of arousals or awakenings.

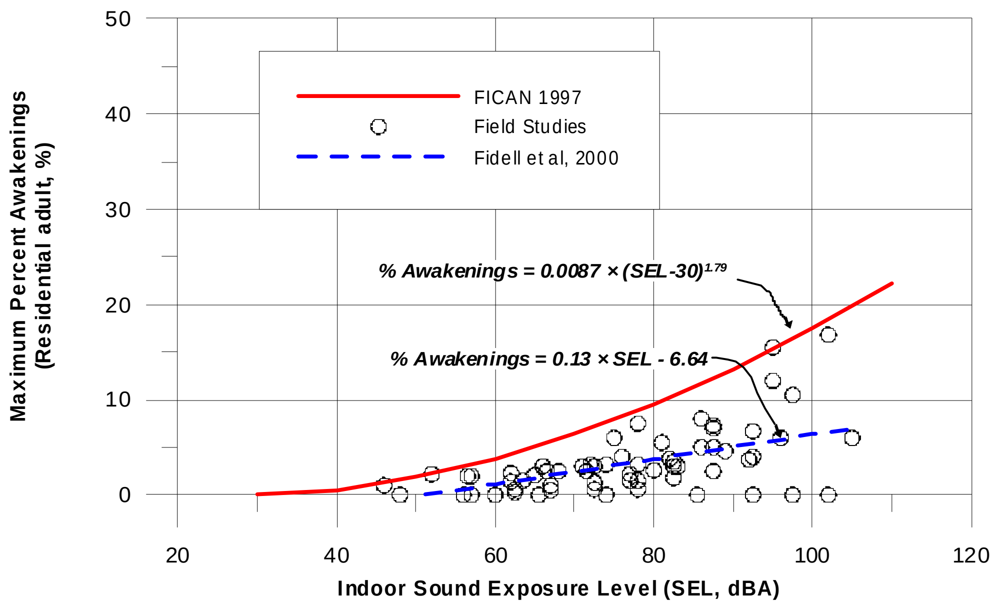
A study performed in 1992 by the Civil Aviation Policy Directorate of the Department of Transportation in the United Kingdom concluded that average sleep disturbance rates (those that are unrelated to outdoor noise) are unlikely to be affected by aircraft noise at outdoor levels below an L_{max} of 80 dBA (Ollerhead, 1992). At higher levels of 80-95 dBA L_{max} the chance of the average person being awakened is about 1 in 75. The study concludes that there is no evidence to suggest that aircraft noise at these levels is likely to increase the overall rates of sleep disturbance experienced during normal sleep. However, the authors emphasize that these conclusions are based on 'average' effects, and that there are more susceptible individuals and there are periods during the night when people are more sensitive to noise, especially during the lighter stages of sleep.

In June 1997, the U.S. Federal Interagency Committee on Aviation Noise (FICAN) reviewed the sleep disturbance issue along with data from the 1992 FICON recommendations (which was primarily the result of many laboratory studies) and presented a new sleep disturbance dose-response prediction curve (FICAN, 1997) as the recommended tool for analysis of potential sleep disturbance for residential areas. The FICAN curve, shown in Figure A-5, was based on data from field studies of major civilian and military airports. For an indoor SEL of 60 dBA, Figure 5 predicts a maximum of approximately 5 percent of the exposed residential population would be behaviorally awakened. FICAN cautions that this curve should only be applied to long-term adult residents.

The focus of this research was the human response to individual SELs rather than the response to multiple events in the same night. The relationship of SEL and percent awakenings presented in the figure is for each event, not a cumulative percent awakening for all events during a sleep period.

Other studies indicate that for a good night's sleep, the number of noise occurrences plays a role as important as the level of the noise. Vallet & Vernet (1991) recommend that, to avoid any adverse effects on sleep, indoor noise levels should not exceed approximately 45 dBA L_{max} more than 10-15 times per night and that lower levels might be appropriate to provide protection for sensitive people. This L_{max} level is equivalent to an SEL of approximately 55 dBA indoors.

FIGURE 5
SLEEP DISTURBANCE DOSE-RESPONSE RELATIONSHIP



Source: FICAN, 1997; Fidell, et. al., 2000;

Griefahn (1978) suggests that awakenings from aircraft overflights are dependent upon the number of events and their sound levels. Figure 6 illustrates Griefahn's compilation of data indicating the number of events and noise level that constitute a threshold for sleep. The data in her research were based on levels at which the most sensitive 10 percent of the population would be disturbed, and includes a correction to these levels to represent the most sensitive sleep state and age group. The lower curve represents the indoor noise level (expressed in terms of L_{max}) and number of noise event combinations at which fewer than 10 percent of the population will show signs of sleep interference. The upper curve indicates the level at which more than 90 percent of the population will be awakened for the given combination of noise levels and noise events. Griefahn suggests that, to avoid any long-term health effects, the upper curve should not be exceeded. The bottom curve represents a preferred, preventative goal. The curves indicate that nearly 90 percent of people will show signs of sleep interference in the presence of 10 to 30 flights per night at an approximate indoor L_{max} of 54 dB. They also show that for the same number of flights but at an indoor L_{max} of 48 dB, the percentage of the most sensitive population affected is much lower, at less than 10 percent, (with 'no reaction' for the less sensitive population).

FIGURE 6
NUMBER OF AWAKENINGS AS A FUNCTION OF MAXIMUM INDOOR NOISE LEVEL

1.3.4 Vibration from Aircraft Operations

The effects of vibration in a residence are observed in two ways; it is felt by the occupant, or it causes physical damage to the structure. Subjective detection can be one of direct perception from rattling of windows and ornaments, or dislodgement of hanging pictures and other loose objects. Structural damage may be either architectural (cosmetic or minor effects) such as plaster cracking, movement or dislodgements of wall tiles, cracked glass, etc., or major, such as cracking walls, complete collapsing of ceilings, etc., which is generally considered to impair the function or use of the dwelling.

Research has shown that vibration can be felt at levels well below those considered to cause structural damage. Complaints from occupants are usually due to the belief that if vibration can be felt, then it is likely to cause damage. Residents living in proximity to airports often complain that aircraft operations cause vibration induced damage to their homes. Research has also shown however, that the slamming of doors or footfalls within a building can produce vibration levels above those produced by aircraft activities (Reverb Acoustics Noise and Vibration Consultants, 2005).

Since people spend the majority of time indoors, the perceptions of aircraft noise leading to annoyance or complaint response and potentially to structural/architectural effects are directly and indirectly affected by the building structure. The acoustic loads resulting from aircraft noise can induce vibration in the structure, which can in turn, result in radiation of noise into its interior, rattling of items in contact with the structure, the perception of the occupants that the structure is vibrating, and the assumption that the vibration is causing structural/architectural effects. Consequently, the response of buildings, particularly older residential structures, to aircraft noise and the resulting effects on human and structural response has been the subject of considerable research.

C-weighted metrics appear to correlate well with subjective evaluations of low frequency noise from aircraft operations (Fidell, et al, 2002; Eagan, 2006). Perceptible wall vibrations in homes are likely to occur for C-weighted levels between 75 and 80 dB (Eagan, 2006). The likelihood of rattle due to low frequency noise increases notably for C-weighted levels within the range of 75 to 80 dB (Hubbard, 1982, Fidell, et. al, 2002). Rattle always occurs above a threshold of roughly 97 dB L_{max} (Hodgdon, 2007). In addition, C-weighting is the only weighting scale currently in the Integrated Noise Model (INM) that addresses low-frequency noise. However, it should be noted that INM predictions are based on extrapolation of A-weighted aircraft sound levels. The same data are used in C-weighted predictions by simply reverse filtering the A-weighted levels. The predictions do not extend to frequencies less than 50 Hz where much of rattle and structural response can be attributed. This is a major limitation of INM C-weighted predictions for vibration assessment.

Generally, fixed-wing subsonic aircraft do not generate vibration levels of a frequency or intensity high enough to result in damage to structures. It has been found that exposure to normal weather conditions, such as thunder and wind, usually have more potential to result in significant structural vibration than aircraft (FAA, 1985). Two studies involving the measurement of vibration levels resulting from aircraft operations upon sensitive historic structures concluded that aircraft operations did not result in significant structural vibration.

1.4 FAA METHODOLOGY FOR EVALUATING AIRCRAFT NOISE

1.4.1 Impact Analysis Criteria and Thresholds

The evaluation of the Key West International Airport (KWIA) airport noise environment was completed using the methodologies and standards specified in title 14 CFR Part 150 (Part 150, 2004). The following paragraphs summarize the pertinent requirements of these documents applicable to conducting a noise analysis and how they were applied in this NEM.

The regulations and guidance documents require that the cumulative noise energy exposure of individuals to noise resulting from aviation activities be established in terms of yearly day/night average sound level (DNL) as the FAA's primary metric. All detailed noise analyses must be performed using the most current version of the FAA's Integrated Noise Model (INM). For this analysis, INM, Version 7.0a, was used to model aircraft noise exposure.

The noise analysis was conducted to reflect current conditions (2008) and forecast conditions (2013). This analysis includes maps and other means to depict land uses within the noise impact area. The addition of flight tracks is helpful in illustrating where aircraft normally fly.

The following information was disclosed for the current conditions (2008) and forecast conditions (2013).

1. The number of people living or residences within each noise contour above DNL 65 for both the Existing and Future Noise Exposure Map (NEM).
2. The location and number of noise sensitive uses (e.g., schools, churches, hospitals, parks, recreation areas) exposed to DNL 65 or greater for both the Existing and Future NEM.
3. Mitigation measures in effect or proposed and their relationship to the Existing and Future NEM.

1.4.2 The Integrated Noise Model

Noise contours generated by the FAA's INM do not depict a strict demarcation of where the noise levels end or begin. Their purpose is to describe the generally expected noise exposure. It must be recognized that although the INM is the current state-of-the-art aircraft noise modeling software, input variables to the INM require several simplifying assumptions to be made, such as: aircraft types flown, flight track utilization, day/night operational patterns, and arrival/departures profiles flown. Further, the noise contours represent average annual conditions rather than single event occurrences. Noise exposure on any one day may be greater or less than the average day. The noise model is useful for comparison of noise impacts between scenarios and provides a consistent and reasonable method to conduct airport noise compatibility planning.

The INM has been the FAA's standard tool since 1978 for determining the predicted noise impact near airports. The FAA developed the INM computer model and it is the required method to predict airport noise contours. The FAA continually enhances the INM to take advantage of increased computer speed, to incorporate new aircraft types into the aircraft noise database, and to improve its noise computation algorithms. INM Version 7.0a was used to produce the noise contours and to analyze noise levels at sensitive sites.

INM includes the capability to turn off lateral attenuation for helicopters and propeller aircraft, in order to simulate propagation over acoustically hard surfaces such as water or rocks. This capability was utilized to take into account the effect of the water surrounding the airport.

The model produces noise exposure contours that are used for land use compatibility maps. Its program includes built in tools for comparing contours and utilities that facilitate easy export to Geographic Information Systems (GIS). The model can also calculate predicted noise at specific sites such as hospitals, schools, or other sensitive locations. For these grid points, the model reports detailed information for the analyst to determine which events contribute most significantly to the noise at that location.

The INM is a computer model that, during an average 24-hour period, accounts for each aircraft flight along flight tracks leading to or from the airport, or overflying the area of interest. Flight track definitions are coupled with information in the program database relating to noise levels at varying distances and flight performance data for each distinct type of aircraft selected. In general, the model computes noise levels at regular grid locations at ground level around the airport and within the area of interest. The distance to each aircraft in flight is computed, and the associated noise exposure of each aircraft flying along each flight track within the vicinity of the grid location is determined. The logarithmic acoustical energy levels for each individual aircraft are then summed for each grid location. The model can create contours of specific noise levels based on the acoustical energy summed at each of the grid points. The cumulative values of noise exposure at each grid location are used to interpolate contours of equal noise exposure. The model can also compute noise levels at user-defined points on the ground.

The noise analyses must be performed using the INM standard and default data, unless there is sufficient justification for modification. Modification to standard or default data requires written approval from the FAA's Office of Environment and Energy (AEE). Standard INM modeling of departure operations begins at the start of takeoff roll and ends when aircraft reach an altitude of 10,000 feet above field elevation (AFE). Standard modeling of arrival operations begins when the aircraft is at an altitude of 6,000 feet and ends when the aircraft land and completes the application of reverse thrust.

All computer model input data should reasonably reflect current and forecasted conditions. User-supplied information required to run the model includes:

- A physical description of the airport layout, including location, length and orientation of all runways, and airport elevation,
- The aircraft fleet mix for the average day,
- The number of daytime flight and run-up operations (7 a.m. to 9:59 p.m.),
- The number of nighttime flight and run-up operations (10 p.m. to 6:59 a.m.),
- Runway utilization rates,
- Primary departure and arrival flight tracks, and

- Flight track utilization rates.

1.4.2.1 Aircraft Operations and Fleet Mix

Fleet mix defines the various types of aircraft and allows development of very specific input data, such as engine type, title 14 CFR part 36 Noise Stage Certification, gross weight, and departure stage length. The INM aircraft database contains actual noise and performance data for 253 types of aircraft. Although the INM aircraft database provides a large selection of aircraft to model, it does not contain every known aircraft. For this reason, the FAA has developed an official aircraft substitution list, containing 259 types of aircraft, which allows the modeler to substitute similar aircraft when necessary for modeling purposes. These substitutions represent a very close estimate of the noise produced by the actual aircraft. All modeled aircraft in this study are either a true representative of an aircraft type or an FAA approved substitution.

1.4.2.2 Time of Day

The time of day that aircraft operations occur is a very important factor in the calculation of cumulative noise exposure. The DNL treats nighttime (10:00 p.m. to 6:59 a.m.) noise differently from daytime (7:00 a.m. to 9:59 p.m.) noise. DNL multiplies each nighttime operation by 10. This weighting of the operations effectively adds 10 dB to the A-weighted levels of each nighttime operation. This weighting factor is applied to account for people's greater sensitivity to nighttime noise. In addition, events during the night are often more intrusive because the ambient sound levels during this time are usually lower than daytime ambient sound levels.

1.4.2.3 Runway Utilization

Runway use refers to the frequency with which aircraft utilize each runway during the course of a year as dictated or permitted by wind, weather, aircraft weight, and noise considerations. The more often a runway is used throughout the year, the more noise is created in areas located off each end of that runway.

1.4.2.4 Flight Tracks and Flight Track Utilization

Flight tracks depict the actual path of aircraft over the ground for aircraft arrival, departure, closed pattern (touch-and-go), and overflight operations. In order to calculate the annual average noise exposure, it is necessary to identify the predominant arrival, departure and pattern flight tracks for each runway, and the number of aircraft that used each runway and flight track. These are significant factors in determining the extent and shape of the noise contours and noise levels at noise-sensitive receptors.

The use of individual flight tracks is dependent on a variety of factors including Air Traffic Control procedures, the aircraft's origin or destination, aircraft performance, weather conditions, and any noise abatement policies.

INM representative flight tracks at KWIA were developed by analyzing radar data, and by field observation. These tracks are meant to be representative of the highest concentration of actual flight tracks at KWIA. Modeled flight tracks do not represent the precise paths flown by all aircraft utilizing KWIA. Instead, they represent the primary flight corridors for the aircraft using the airport.

1.4.2.5 Aircraft Profiles

The INM default database includes profiles modeling aircraft departures up to 10,000 feet above field elevation (AFE) and arrivals from 6,000 feet AFE.

Arrival Profiles

The INM contains one approach profile for most standard aircraft, which represents a 3-degree descent from an altitude of 6,000 feet above field elevation. Some standard general aviation aircraft also have an approach profile representing a 5-degree descent. The assumptions used in the INM are based upon "average" operational data; flight procedures etc. and standard practice is to assign standard 3-degree INM approach profiles. All arrival profiles used in this study are INM default profiles.

Departure Profiles

The INM relies on the trip length of a given flight to determine the departure weight and associated departure profile. Default procedural profiles are assumed. Three default procedural profiles are available, these are the "Standard," "ICAO-A," and "ICAO-B" departure profiles. The assumptions used in the INM are based upon "average" operational data; aircraft passenger load factors, fuel reserves, flight procedures etc. and standard practice is to assign INM profiles based on trip length. In some cases, the analysis of aircraft departure weight is also used. All departure profiles used in this study are INM default profiles, and stage length is based on trip length.

1.4.2.6 Departure Stage Length

The INM database contains several departure profiles for each fixed-wing aircraft type representing the varying performance characteristics for that aircraft at a particular takeoff weight. Use of appropriate departure profiles is an important component of calculating DNL noise exposure contours. Historically, it has been easier to obtain trip length data than average weight data, so the INM uses "departure stage length" to best represent typical aircraft takeoff weight.

Departure stage length is the distance between the departure airport and the destination airport. As the departure stage length increases, the aircraft's required fuel load and takeoff weight also increase. The increase in takeoff weight equates to a decrease in aircraft takeoff and climb performance. A decrease in aircraft performance results in a longer takeoff departure roll and decreased climb rates. These performance characteristics produce increased noise exposure impacts. The aircraft's noise impacts are greater because the aircraft is producing noise closer to the ground longer. The departure stage lengths are defined in Table 1.

TABLE 1
INM 7.0 STAGE LENGTH DISTANCES

Stage Number	Distance (nm)
1	0-500
2	501-1,000
3	1,001-1,500
4	1,501-2,500
5	2,501-3,500
6	3,501-4,500
7	4,501-5,500
8	5,501-6,500
9	> 6,500

Source: FAA INM Version 7.0 User's Guide

1.4.2.7 Noise Model Outputs

INM has many output capabilities. Charts, graphics, and tables can be viewed, exported, or printed. The most common outputs are the noise contours that INM produces. Additionally, there are many other outputs, such as aircraft performance characteristics, grid point analyses for several noise metrics, and input characteristics such as runways and flight tracks. A complete description of model outputs can be found in the INM Users Guide (FAA, 2007).

Appendix C. Air Quality Analysis Report
(prepared by JJR/April 2009)

Technical Memorandum: Air Quality Analysis
Ann Arbor Municipal Airport Environmental Assessment

April 9, 2009
JJR No. 50178.000

Pollutant Health Effects

Air pollutants are contaminants in the atmosphere. Many man-made pollutants are a direct result of the incomplete combustion of fuels including coal, oil, natural gas, and gasoline. The principal factors affecting air pollution concentrations with respect to transportation projects are traffic, emissions factors, roadway type, terrain, meteorological parameters, and ambient air quality. The air pollutants listed here are the most common when dealing with transportation projects.

Carbon Monoxide (2006 Annual Air Quality Report for Michigan, MDEQ, page 4)

Carbon monoxide (CO) is a colorless, odorless, and poisonous gas created when fuel does not burn completely. The primary sources for outdoor exposure to CO are the exhaust from automobiles, industrial processes, non-transportation fuel combustion, and natural sources such as forest fires. Elevated levels of CO can cause visual impairment, interfere with mental acuity, and decrease work performance in the completion of complex tasks. High CO pollution levels can affect anyone; however, people who suffer from cardiovascular disease are most at risk.

Ozone (2006 Annual Air Quality Report for Michigan, MDEQ, page 5)

Ozone (O_3), a key ingredient in urban smog is created at ground-level by photochemical reactions involving nitrogen oxides (NO_x) and volatile organic compounds (VOCs) in the presence of sunlight. Major sources of NO_x and VOCs are engine exhaust, emissions from industrial facilities, combustion from power plants, gasoline vapors, chemical solvents, and biogenic emissions from natural sources. Elevated O_3 exposure can irritate a person’s airways, reduce lung function, aggravate asthma and chronic lung diseases, and inflame and damage the cells lining the lungs. O_3 may also reduce the immune system’s ability to fight off bacterial infections in the respiratory system, and long-term, repeated exposure may cause permanent lung damage.

Nitrogen Dioxide (2006 Annual Air Quality Report for Michigan, MDEQ, page 5)

Nitrogen dioxide (NO_2) is a highly reactive gas that is formed through the oxidation of nitric oxide. The major sources of man-made NO2 emissions come from high-temperature combustion processes. Evidence suggests that long-term exposures to NO2 may lead to increased susceptibility to respiratory infection and may cause structural alterations in the lungs.

Particulate Matter (2006 Annual Air Quality Report for Michigan, MDEQ, page 6)

Particulate Matter (PM) is a general term used for a mixture of solid particles and liquid droplets found in the air which is further categorized according to size. PM_{10} are “coarse particles” less than 10 μm in diameter and $PM_{2.5}$ are much smaller “fine particles” equal to or less than 2.5 μm in diameter. PM_{10} consists of primary particles that can originate from power plants, various manufacturing processes, wood stoves and fireplaces, fugitive dust sources, and forest fires. $PM_{2.5}$ can come directly from primary particle emissions or through secondary reactions that include VOCs, SO_2, and NO_x emissions originating from power plants, motor vehicles, industrial facilities, and other types of combustion sources. Exposure to PM affects breathing and the cellular defenses of the lungs, aggravates existing respiratory and cardiovascular ailments, and has been linked with heart and lung disease.

Sulfur Dioxide (2006 Annual Air Quality Report for Michigan, MDEQ, page 6)

Sulfur dioxide (SO_2) is formed by the burning of sulfur-containing material and can react with other atmospheric chemicals to form sulfuric acid. In liquid form, it is found in clouds, fog, rain, aerosol particles, and in surface films on these particles. Coal burning power plants are the largest source of SO_2 emissions. SO_2 is also emitted from smelters, petroleum refineries, pulp and paper mills, transportation sources, and steel mills. Where SO_2 is emitted, PM is often emitted too. Exposure to elevated levels of SO_2 aggravates existing cardiovascular and pulmonary disease. SO_2 and PM together may cause respiratory illness, alteration in the body's defense and clearance mechanisms, and aggravation of existing cardiovascular disease. SO_2 and NO_x together are the major precursors to acid rain, which is associated with the acidification of soils, lakes, and streams and accelerated corrosion of buildings and monuments.

Lead (2006 Annual Air Quality Report for Michigan, MDEQ, page 4)

Lead (Pb) is a highly toxic metal found in coal, oil, and waste oil. It is also found in municipal solid waste and sewage sludge incineration and may be released to the atmosphere during their combustion. The highest air concentrations of Pb are found in the vicinity of smelters and battery manufacturers. Other industrial sources include Pb glass, Portland cement, and solder production. Pb primarily accumulates in the blood, bones, and soft tissues of the body, and can adversely affect the kidneys, liver, nervous system, and other organs.

Regulatory Standards

The Clean Air Act of 1970, the 1977 Clean Air Act Amendments and the 1990 Clean Air Act Amendments (CAAA) are the applicable regulations that govern air quality for the project area. Under the CAAA, the U. S. Department of Transportation cannot fund, authorize, or approve Federal actions to support programs or projects that are not first found to conform to the Clean Air Act requirements. The air quality provisions of the Clean Air Act (CAA), as amended, are intended to ensure the integration of air quality planning in all transportation-related projects.

The establishment of the National Ambient Air Quality Standards (NAAQS) by the Environmental Protection Agency (EPA) was directed in the Clean Air Act, and their attainment and maintenance was reinforced in later amendments. The goal of air quality monitoring and actions is to ensure that the air quality levels of the various pollutants do not exceed the set standards. These standards are summarized in Table 1.

Table 1: National Ambient Air Quality Standards (NAAQS)

Criteria Pollutant	Primary (Health Related)		Secondary (Welfare Related)	
	Type of Average	Standard Level Concentration	Type of Average	Standard Level Concentration
Carbon Monoxide, CO	8-hour 1-hour	9 ppm (10 mg/m^3) 35 ppm (40 mg/m^3)	No Secondary Standard	
Lead, Pb	Maximum Quarterly Average	1.5 μg/m^3	Same as Primary Standard	
Nitrogen Dioxide, NO_2	Annual Arithmetic Mean	0.053 ppm (100 μg/m^3)	Same as Primary Standard	
Ozone, O_3	4th Highest 8-Hour Daily Maximum	0.085 ppm (157 μg/m^3)	Same as Primary Standard	
Particulate Matter, PM_{10}	24-Hour	150 μg/m^3	Same as Primary Standard	
Particulate Matter, $PM_{2.5}$	Annual Arithmetic Mean	15 μg/m^3	Same as Primary Standard	
	98th percentile 24-hour	35 μg/m^3		
Sulfur Dioxide, SO_2	Annual Arithmetic Mean	0.03 ppm (80 μg/m^3)	3-Hour	0.5 ppm (1300 μg/m^3)
	24-Hour	0.14 ppm (365 μg/m^3)		

Attainment Status

The Air Quality Division of the Michigan Department of Environmental Quality (MDEQ) produces an Annual Air Quality Report, which outlines the attainment status of the state. According to the 2006 Air Quality Report the project study area is in attainment with the NAAQS for ambient concentrations of carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and coarse particulate matter (PM_{10}).

Ozone

All Michigan counties are now designated as attainment for the 1-hour O_3 NAAQS. The 1-hour standard has since been revoked by the EPA. In 1997, EPA issued the average-based 8-hour ozone NAAQS (attained when the 3-year average of the 4th highest value is below 0.085 ppm). In 2004, utilizing 2001-2003 monitoring data, EPA designated 25 counties in Michigan as nonattainment for the 8-hour O_3 NAAQS, of which Washtenaw County was included. A nonattainment designation indicates that the area does not meet the national health-based standard, or contributes to violations of the standard in another area. Upon review of the O_3 data collected for the period of 2004-2006, Washtenaw County is now meeting the 8-hour O_3 NAAQS and is designated as marginal nonattainment. The MDEQ Air Quality Division has requested re-designation of Washtenaw County to attainment

Particulate Matter

EPA promulgated the $PM_{2.5}$ NAAQS on July 18, 1997. In the January 5, 2005 Federal Register (FR), EPA announced their $PM_{2.5}$ designations, effective April 5, 2005, utilizing the 2001-2003 three year annual average data. Based upon this data, Washtenaw County was designated as nonattainment for $PM_{2.5}$. As stated in the FR notice, States were allowed to submit 2004 $PM_{2.5}$ quality-assured monitoring data, calculate the 2002-2004 three-year annual average, and request changes in attainment status if this data and supporting rationale showed an area should instead be designated attainment.

On February 22, 2005, MDEQ submitted documentation demonstrating that monitors in the counties surrounding Wayne County (Livingston, Oakland, Macomb, Monroe, St. Clair, and Washtenaw Counties) are not violating the standard and that Wayne County is the only county showing nonattainment. The MDEQ submittal also included information supporting the conclusion that air pollution emissions in the surrounding six counties do not cause the nonattainment levels in Wayne County. However, the EPA denied Michigan's request for reconsideration as they believe the surrounding counties contribute to the overall air quality violations at the Wayne County monitors. The Southeast Michigan Council of Governments (SEMCOG) and the MDEQ are currently developing an emissions control strategy to bring the region into attainment by 2010 as required by the EPA.

Air Traffic Modeling Parameters

The Federal Aviation Administration (FAA) created the Air Quality Procedures for Civilian Airports & Air Force Bases in an effort to aid in assessing the impacts at airports and air bases. Included in the procedures is a flow chart that can be used to determine whether a NAAQS analysis is required. The first step in the flow chart is to determine whether the proposed action is located in a nonattainment or maintenance area. As stated previously, the project area is currently designated as marginal nonattainment for ozone and nonattainment for particulate matter.

Since the project area is in a nonattainment area the next step is to determine whether the proposed project is exempt or presumed to conform. For this analysis, it will be assumed that the project is neither exempt nor presumed to conform.

The next step is to determine whether direct emissions will occur as a result of the proposed project. The FAA defines a direct emission as "an effect that is caused by the implementation and/or operation of an action that occurs at the same time and place" (Air Quality Procedures for Civilian Airports & Air Force Bases, 1997, page xvi). The proposed project is the extension of an existing runway. It can be assumed that direct emissions are already occurring and will increase as a result of increased usage of the airport.

Once it is determined whether direct emissions are occurring, it needs to be determined whether indirect emissions are reasonably feasible as a result of the proposed project. The FAA defines an indirect emission as "those caused by the implementation and/or operation of an action, are reasonably foreseeable, but which occur later in time and/or are farther removed in distance from the action itself" (Air Quality Procedures for Civilian Airports & Air Force Bases, 1997, page xviii). For this project, it can be assumed that no indirect emissions will occur. Therefore, the total emissions are equal to the direct emissions.

After determining whether any indirect emissions occur, an analysis of the airport activity is examined. The Ann Arbor Municipal Airport is considered to be a general aviation airport. For this type of airport, if the activity is forecasted to be 180,000 yearly operations, an NAAQS assessment is required. The yearly activity for the AAMA is expected to be approximately 70,000 operations per year. Consequently, an NAAQS assessment will not be required.

After examining the direct and indirect emissions, a conformity assessment may also need to be performed based on whether the net emissions exceed general conformity threshold levels and are regionally significant. The Michigan Department of Transportation Bureau of Aeronautics completed the Michigan Airports Air Quality Study in May 1996. In this study, an air pollutant emission inventory was created for seven general aviation airports based on their proposed development. The air pollutant emission inventory indicates that the emissions from all of the airports studied would be well below the general conformity threshold rates. Since the AAMA is comparable in size and activity to the seven airports studied, it can be assumed that the emissions resulting from the proposed project will not exceed the general conformity threshold levels and will not be regionally significant. Therefore, a conformity determination is not required and the proposed project is presumed to conform to the state implementation plan.

Automobile Modeling Parameters

As stated previously, Washtenaw County is designated as being in attainment with the NAAQS for carbon monoxide. The primary NAAQS for CO are 35 parts per million (ppm) for the maximum one-hour concentration, and nine ppm for the maximum eight-hour concentration. To be in attainment with the NAAQS, these concentrations may not be exceeded more than once annually at a given site. In order to determine whether the proposed project will be in attainment with the NAAQS, a micro-scale air quality analysis was conducted. Through this analysis, maximum one-hour CO concentrations for the Existing Condition (2008) and the No Build Condition and Proposed Alternative in the design year (2030) were estimated.

The calculation of CO concentrations was performed through the use of two computer models. The first model, MOBILE6.2.03, developed by the Environmental Protection Agency (EPA), provided the means for calculating vehicular emission factors for the range of expected vehicle types. The second model CAL3QHC, which is also known as the California Line Source Dispersion Model is used to calculate CO concentrations at receptor sites. The EPA has improved upon this program in order to allow analysis of air quality conditions at road intersections, where highest concentrations of pollutants are typically found.

The emission factors determined through MOBILE6.2, in addition to receptor locations, peak hourly traffic volumes, meteorological conditions and roadway geometry constituted the input data for CAL3QHC. The aforementioned parameters were conservatively selected in order to represent a worst-case scenario for each of the conditions. Background CO concentrations were obtained from the MDEQ's 2006 Air Quality Report.   Since there is not a single monitoring site near the project site, the average of the highest recorded value for all nine sites was used for the background concentrations. The resulting one-hour background concentration used in the model was 3.0 ppm.

Locations along the various road corridors were selected for analysis of air quality conditions. Locations were chosen based upon existing traffic volumes and future projections, nearby proximity of sensitive receptors, and representative location within the overall project vicinity. Layout plans, air photos, and site observations were used to determine the locations of sensitive receptors near the studied intersections. The sensitive receptors included residential properties and open spaces (see Figure X).

Traffic volumes were obtained from the SEMCOG website and the Washtenaw Area Transportation Study (WATS) website for the existing condition. WATS also determined the increase in the traffic volumes for the future conditions. According to their models, State Street and Lohr Road will experience a cumulative increase in traffic volume of 3.3% for the future condition. Similarly, Ellsworth Road will experience a cumulative increase in traffic volume of 3.7% for the future condition.

A persistence factor is the ratio between the 8-hour and 1-hour CO concentration and is used to estimate the 8-hour CO concentration based on the 1-hour CO concentration. Three seasons of monitoring data were obtained from the MDEQ's Air Quality Reports and are tabulated in Table 2. The persistence factor for each station and each year was calculated by dividing the 8-hour CO concentration by the 1-hour CO concentration. The average of all of the persistence factors was calculated to be 0.70, which compares well with tabulated values for urban locations. Therefore, the 8-hour CO concentrations were determined by multiplying the persistence factor of 0.70 by the 1-hour CO concentrations as calculated by CAL3QHC.

Table 2: Persistence Factor

Station	One-Hour CO Concentration (ppm)			Eight-Hour Concentration (ppm)			Persistence Factor		
	2004	2005	2006	2004	2005	2006	2004	2005	2006
Otisville	1.1	--	--	0.6	--	--	0.55	--	--
Grand Rapids	3.0	2.8	2.7	2.2	2.0	2.0	0.73	0.71	0.74
Warren	3.3	4.8	3.5	2.1	2.5	3.0	0.64	0.52	0.86

Category Average	3.0			2.1			0.70		

Automobile Modeling Results

Existing Condition

CAL3QHC was used with the existing road centerlines and traffic volumes to determine one-hour CO levels. The maximum one-hour CO concentration is 5.2 ppm and the average concentration is 3.6 ppm. No receptors exceed the NAAQS one-hour standard of 35 ppm. The persistence factor calculated previously was used to determine the eight-hour CO concentrations from the one-hour concentrations. The resulting maximum eight-hour concentration is 3.6 ppm and the average concentration is 2.5 ppm. No receptors exceed the NAAQS eight hour standard of 9 ppm.

No-Build Condition

The increased traffic volumes (as determined by WATS) were adjusted in the CAL3QHC model to the 2030 values to determine the future CO concentrations. With the increased traffic, the model shows that there will be no significant increase in the CO concentrations. The maximum one-hour concentration remains at 5.2 ppm, and the maximum eight-hour concentration remains at 3.6 ppm. No receptors exceed the NAAQS one-hour or eight-hour standards. The average one-hour CO concentration is 3.6 ppm, the average eight-hour CO concentration is 2.5 ppm, both of which are identical to the averages for the Existing Condition. Twenty seven receptors experience an increase in one-hour and eight-hour concentrations with a maximum one-hour increase of 0.3 ppm and a maximum eight-hour increase of 0.2 ppm.

Consequences of the Preferred Alternative
There will be no revisions to the existing roadway system as a result of the Preferred Alternative. Consequently, the air model results for the Preferred Alternative will be identical to those for the No-Build Condition. Since the No-Build Condition analysis shows that no sites will exceed the one-hour or eight-hour NAAQS standard, the Preferred Alternative also will have no sites exceeding the NAAQS standard.

During construction, appropriate mitigation measures, such as covering and spraying stock piles with water, should be utilized to minimize potential short term negative impacts which may be experienced locally due to fugitive dust, construction vehicle exhaust, or other fumes related to construction materials and equipment.

Affected Environment

Climate Change/Greenhouse Gases

Of growing concern is the impact of proposed projects on climate change. Greenhouse gases are those that trap heat in the earth's atmosphere. Both naturally occurring and anthropogenic (man-made) greenhouse gases include water vapor (H_2O), carbon dioxide (CO_2),[1] methane (CH_4), nitrous oxide (N_2O), and ozone (O_3).[2]

Research has shown that there is a direct link between fuel combustion and greenhouse gas emissions. Therefore, sources that require fuel or power at an airport are the primary sources that would generate greenhouse gases. Aircraft are probably the most often cited air pollutant source, but they produce the same types of emissions as cars. Aircraft jet engines, like many other vehicle engines, produce carbon dioxide (CO_2), water vapor (H_2O), nitrogen oxides (NO*x*), carbon monoxide (CO), oxides of sulfur (SO*x*), unburned or partially combusted hydrocarbons (also known as volatile organic compounds (VOCs)), particulates, and other trace compounds.

According to most international reviews, aviation emissions comprise a small but potentially important percentage of anthropogenic (human-made) greenhouse gases and other emissions that contribute to global warming. The Intergovernmental Panel on Climate Change (IPCC) estimates that global aircraft emissions account for about 3.5 percent of the total quantity of greenhouse gas from human activities.[3] In terms of U.S. contribution, the U.S. General Accounting Office (GAO) reports that aviation accounts "for about 3 percent of total U.S. greenhouse gas emissions from human sources" compared with other industrial sources, including the remainder of the transportation sector (23 percent) and industry (41 percent).[4]

---

[1] All greenhouse gas inventories measure carbon dioxide emissions, but beyond carbon dioxide different inventories include different greenhouse gases (GHGs).
[2] Several classes of halogenated substances that contain fluorine, chlorine, or bromine are also greenhouse gases, but they are, for the most part, solely a product of industrial activities. For example, chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs) are halocarbons that contain chlorine, while halocarbons that contain bromine are referred to as bromofluorocarbons (i.e., halons) or sulfur (sulfur hexafluoride: SF_6).
[3] IPCC Report as referenced in U.S. General Accounting Office (GAO) *Environment: Aviation's Effects on the Global Atmosphere Are Potentially Significant and Expected to Grow*; GAO/RCED-00-57, February 2000, p. 4.
[4] Ibid, p. 14; GAO cites available EPA data from 1997.

The scientific community is developing areas of further study to enable them to more precisely estimate aviation's effects on the global atmosphere. The FAA is currently leading or participating in several efforts intended to clarify the role that commercial aviation plays in greenhouse gases and climate change. The most comprehensive and multi-year program geared towards quantifying climate change effects of aviation is the Aviation Climate Change Research Initiative (ACCRI) funded by FAA and NASA. ACCRI will reduce key scientific uncertainties in quantifying aviation-related climate impacts and provide timely scientific input to inform policy-making decisions. FAA also funds Project 12 of the Partnership for AiR Transportation Noise & Emissions Reduction (PARTNER) Center of Excellence research initiative to quantify the effects of aircraft exhaust and contrails on global and U.S. climate and atmospheric composition. Finally, the Transportation Research Board's (TRB) Airport Cooperative Research Program (ACRP) project 02-06 is preparing a guidebook on preparing airport greenhouse gas emission inventories. The results of this effort are expected to be out in late 2008.

Environmental Consequences

Based on FAA data, operations activity at the Ann Arbor Municipal Airport represents less than 0.1 percent of U.S. aviation activity. Therefore, assuming that greenhouse gases occur in proportion to the level of activity, greenhouse gas emissions associated with existing and future aviation activity at the Ann Arbor Municipal Airport would be expected to represent less than 0.1 percent of U.S.-based greenhouse gases. Therefore, we would not expect the emissions of greenhouse gases from this project to be significant.

Cumulative Effects

Because aviation activity at the Ann Arbor Municipal Airport represents such as small amount of U.S. and global emissions, and the related uncertainties involving the assessment of such emissions regionally and globally, the incremental contribution of this proposed action cannot be adequately assessed given the current state of the science and assessment

RE: Proposed Environmental Assessment for Ann Arbor Municipal Airport

Dear Ms Eckland:

The location of the proposed project was checked against known localities for rare species and unique natural features, which are recorded in a statewide database. This continuously updated database is a comprehensive source of information on Michigan's endangered, threatened and special concern species, exemplary natural communities and other unique natural features. Records in the database indicate that a qualified observer has documented the presence of special natural features at a site. The absence of records may mean that a site has not been surveyed. The only way to obtain a definitive statement on the presence of rare species is to have a competent biologist perform a field survey.

Under Act 451 of 1994, the Natural Resources and Environmental Protection Act, Part 365, Endangered Species Protection, "a person shall not take, possess, transport, ...fish, plants, and wildlife indigenous to the state and determined to be endangered or threatened," unless first receiving an Endangered Species Permit from the Department of Natural Resources, Wildlife Division. *Responsibility to protect endangered and threatened species is not limited to the list below. Other species may be present that have not been recorded in the database.*

The presence of threatened or endangered species does not preclude activities or development, but may require alterations in the project plan. Special concern species are not protected under endangered species legislation, but recommendations regarding their protection may be provided. Protection of special concern species will help prevent them from declining to the point of being listed as threatened or endangered in the future.

The following is a summary of the results for the project in Washtenaw County, sections 16, 17, T3S R6E.

The following list includes unique features that are known to occur on or near the site(s) and may be impacted by the project.

common name	status	scientific name
Henslow's sparrow	**state endangered**	***Ammodramus henslowii***
Grasshopper sparrow	**special concern**	***Ammodramus savannarum***

The **Henslow's sparrow** has been known to occur in the area. Henslow's sparrow require grasslands to breed. Today, this means grassy fields, pastures, hayfields and meadows with

STEVENS T. MASON BUILDING • P.O. BOX 30028 • LANSING, MICHIGAN 48909-7528
www.michigan.gov/dnr • (517) 373-2329

scattered shrubs. They are often found in damp/moist low-lying locations. Henslow's arrive in Michigan in early April and are on their breeding ground by late to early May. Two broods are common during the breeding season, which means nesting can last into August. Fall migration begins in late September to mid-October.

The **grasshopper sparrow** has been known to occur in the area. Grasshopper sparrow's can be found in native prairies, cultivated fields, old fields, hayfields, pastures and open savanna. The nest is generally well concealed on the ground by overhanging vegetation. Spring arrival occurs in April and May and by mid-May grasshopper sparrow's are on their breeding ground. Two broods are a possible during the breeding season, which means nesting can last into August. Fall migration is complete by late October.

In summary, the project site may include suitable habitat for the above listed species. Potential impacts might include direct destruction of species and disturbance of critical habitat.

Thank you for your advance coordination in addressing the protection of Michigan's natural resource heritage. If you have further questions, please call me at 517-373-1263 or e-mail at SargentL@michigan.gov .

Re: Early Coordination for Proposed Improvements at Ann Arbor Municipal Airport, Washtenaw County, Michigan

Dear Ms. Lamrouex:

We are responding to your May 4, 2009, request for early coordination regarding the subject project. We submit these comments in accordance with section 7 of the Endangered Species Act of 1973, as amended (Act), and the National Environmental Policy Act (NEPA).

Wetlands

For information on the location of wetlands, please visit the National Wetland Inventory (NWI) wetland map website (National Map Viewer) at *http://nmviewogc.cr.usgs.gov/viewer.htm*. Pursuant to state law and the federal Clean Water Act, the State of Michigan regulates certain activities in wetlands. Development that would impact wetlands may require a permit for which this office may have review authority. In the review of these permit applications, we may concur (with or without stipulations) or object to permit issuance depending upon whether the proposed work may impact public trust fish and wildlife resources.

Migratory Birds

Under the Migratory Bird Treaty Act of 1918, as amended, it is unlawful to take, capture, kill, or possess migratory birds, their nests, eggs, and young. For proposed projects that may contain habitat suitable for nesting by migratory bird species, including song birds and/or raptors, we recommend you schedule construction activities or remove potential habitat or nesting structures before the initiation of spring nesting or after the breeding season has ended to avoid take of migratory birds, eggs, young, and/or active nests. Generally, we recommend that any habitat disturbance occur before April 15 or after August 1 to minimize potential impacts to migratory birds, but please be aware that some species may initiate nesting before April 15.

Scanned 6-8-09

Endangered Species

For endangered and threatened species list requests and section 7 consultations with the U.S. Fish and Wildlife Service, please refer to our endangered species and technical assistance website, located at *http://www.fws.gov/midwest/endangered/section7/index.htm*. In some cases, you may be able to conclude the endangered species review process without contacting this office.

We appreciate the opportunity to provide comments at this early stage of project planning. Please direct any questions to Barbara Hosler of this office at 517/351-6326 or the above address.

Sincerely,

Barbara Hosler

Dear Ms. Eckland:

RE: Ann Arbor Municipal Airport – JJR Project No. 50178.000

Our office has reviewed your request dated March 30, 2009 regarding the above-referenced project and finds that there are no Farmland Development Rights Agreements on any property within the project boundaries.

Therefore, we conclude that there will be no project impacts on land enrolled in this program.

Thank you for the opportunity to review this project.

Sincerely,

Jarrod Thelen, Resource Analyst

Aeronautics and Freight Services
2700 Port Lansing Road
Lansing, Michigan 48906

Dear Ms. Lamrouex:

SUBJECT: Michigan Department of Environmental Quality (MDEQ) File Number 09-81-5002
Early Coordination – Ann Arbor Municipal Airport, Washtenaw County, Michigan

The MDEQ, Land and Water Management Division (LWMD) has completed review of your May 4, 2009, request for early coordination comments for the Ann Arbor Municipal Airport located in Section 17, T3S, R6E, of Washtenaw County, Michigan. Your letter indicates that you are in the process of preparing an Environmental Assessment (EA) for the proposed project, which includes determining the feasibility of shifting and extending the primary runway and parallel taxiway 950 feet to the southwest. Based on the general information provided, we have the following comments.

1) All natural resource features, including lakes, streams, and wetlands, should be identified as part of your investigation. Any alternatives that are developed need to evaluate the potential impact on these and other resources. Steps should be taken to identify feasible and prudent alternatives to avoid and/or minimize any potential impacts to the natural resources.

2) There appears to be a drain/stream located at the southwest corner of the airport property. Any impacts to this drain/stream would require a permit under Part 301, Inland Lakes and Streams, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA). Under Part 301, we recommend that new structures fully span the bankfull channel when feasible. Our preference is for streams or drains to be relocated instead of enclosed where the impacts can not be avoided.

3) The drainage area of the small drain is less than 2 square miles; therefore, a permit would not be required under the State's Floodplain Regulatory Authority found in Part 31, Water Resources Protection, of the NREPA.

4) It is not clear if any wetlands would be impacted by the proposed project. Available maps do appear to indicate the presence of hydric soils near the airport. If there are wetlands impacts, they should be field verified, and their types, functions, and values properly described. Impacts to wetlands will require a permit under Part 303, Wetlands Protection, of the NREPA. Mitigation will be required for any unavoidable impacts to wetlands. We do not regulate the clearing of vegetation but would require a permit under Part 303, Wetlands Protection, of the NREPA for any grading, filling, draining, or

grubbing where stumps are removed. Cut vegetation should be removed from any wetland areas. Additional information on wetlands and the mitigation requirements can be found at www.michigan.gov/deqwetlands.

5) A special interest search of our databases indicates that there is a potential State Threatened plant and Endangered animal in section 17, T3S, R6E. If these species are within your project area, you will be required to coordinate the potential impacts with Ms. Lori Sargent, Michigan Department of Natural Resources, at 517-373-9418.

6) Our database search also indicates potential Part 201 sites located in section 17, T3S, R6E. Please contact Mr. Mitch Adelman at 517-780-7690 of the Remediation and Redevelopment Division in the LWMD's Jackson District Office for further information.

7) A National Pollution Discharge Elimination System (NPDES) permit will be required for storm water discharges associated with construction activities in accordance with Rule 2190 promulgated in accordance with Part 31, Water Resources Protection, of the NREPA.

8) A permit will be required under Part 91, Soil Erosion and Sedimentation Control, of the NREPA. Part 91 permits are generally issued by the county or, in some instances, the local municipality. If the earth change involves two or more Part 91 permitting entities, the MDEQ issues the Part 91 permit.

As the project planning becomes better defined, we may have additional comments.

Thank you for the opportunity to review and provide comments. If you have any questions or need to schedule a field review, please contact Mr. Alex Sanchez at 517-335-3473, or you may contact me.

Sincerely,

Gerald W. Fulcher, Jr., P.E., Chief

Dear Ms. Lamrouex:

SUBJECT: Express Wetland Identification Report
Wetland Identification File Number: 09-81-0001-WA

The Department of Environmental Quality (DEQ) conducted a Level 2 Express Wetland Identification Review of 5 acres of an approximately 300-acre property (Property Tax Identification Number Ann Arbor Municipal Airport) located in Town 03S, Range 06E, Section 17, Pittsfield Township, Washtenaw County on July 21, 2009. The wetland review was conducted in accordance with Part 303, Wetlands Protection, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA); and Rule 4 (1), Wetland Identification and Assessment (R 281.924) of the Administrative Rules for Part 303. This is a report of our findings in response to your Wetland Identification Application.

Based on our site review, which included a review of the dominant vegetation, hydrology, and soils, as well as an in-office review of pertinent information, the DEQ finds that the 5-acre review area does not contain wetland regulated by the state. The wetland within the review area is not regulated by the state since it is not within 500 feet of an inland lake or stream or within 1,000 feet of the Great Lakes or their connecting waters. The DEQ lacks jurisdiction under Part 303 for activities occurring within the Wetland Identification Review area.

Please be aware that this Wetland Identification Report does not constitute a determination of the presence of wetland that may be regulated under local ordinances or federal law. The U.S. Army Corps of Engineers (USACE) retains regulatory authority over certain wetlands pursuant to Section 404 of the Clean Water Act (CWA), and specifically those wetlands associated with navigable waters of the state. Navigable waters are generally the Great Lakes, their connecting waters, and portions of river systems and lakes connected to these waters. In other areas of the State, the DEQ is responsible for identification of wetland boundaries for purposes of compliance with the CWA under an agreement with the U.S. Environmental Protection Agency.

Your Wetland Identification Review area does not appear to be within those areas regulated by the USACE. However, should you desire more information, please contact the USACE at 313-226-2218.

This Wetland Identification Report is limited to findings pursuant to Part 303 and does not constitute a determination of jurisdiction under other DEQ administered programs. Any land use activities undertaken within the review area may be subject to regulation pursuant to the NREPA under the following parts.

Floodplain Regulatory Authority found in Part 31, Water Resources Protection
Part 91, Soil Erosion and Sedimentation Control
Part 301, Inland Lakes and Streams

The findings contained in this report do not convey, provide, or otherwise imply approval of any governing act, ordinance, or regulation, nor does it waive the obligation to acquire any applicable state, county, local, or federal approvals. This Wetland Identification Report is not a permit for any activity that requires a permit from the DEQ.

The findings contained in this report are binding on the DEQ until July 21, 2012, a period of three years from the date of this Wetland Identification Report. Please contact me if you have any questions regarding this report.

Sincerely,

Peg Bostwick for

Re: Request for Early Coordination Review of Proposed Improvements for the Ann Arbor Municipal Airport, Washtenaw County, Michigan

Dear Ms. Lamrouex:

The NEPA Implementation Section has received you May 4, 2009 letter requesting information for the Ann Arbor Municipal Airport, Washtenaw County, Michigan. Under the National Environmental Policy Act (NEPA) and Section 309 of the Clean Air Act; U.S. EPA reviews and comments on major federal actions and other actions with environmental impacts when resources permit.

We understand the project will likely include a shift and extension of the primary runway and the parallel taxiway 950 feet to the southwest. Based on the information that you provided to us it is likely that the project will impact wetlands and forested areas.

As with any project, it is important to avoid impacts to wetlands and other natural resources. EPA and other resource agencies will assume that there are other alternatives that reduce environmental impacts, especially if the project is likely to adversely impact high quality wetlands and other natural resources. Therefore, we encourage you to thoroughly explain the project's purpose and need and rigorously explore alternatives that either do not affect or otherwise minimizes impacts to sensitive resources such as wetlands, floodplains, and streams.

Please provide us with information about this project as it progresses. Please contact Ms. Sherry Kamke at 312-353-5794 if you have any questions.

Sincerely,

Kenneth A. Westlake, Supervisor

RE: Ann Arbor Municipal Airport

Dear Eckland,

The Farmland Conversion Impact Rating form (AD-1006) for the proposed Ann Arbor Municipal Airport runway expansion is attached. The portions of the form to be filled out by NRCS are completed.

Some prime and farmland of local importance would be impacted by this project. If the project proceeds, I would urge you to utilize NRCS standards and specifications for conservation practices, as listed in the NRCS Electronic Field Office Technical Guide. This may be found at www.mi.nrcs.usda.gov.

Please don't hesitate contacting me if you have any questions.

RE: ER-5410 Ann Arbor Municipal Airport – Runway Extension, Section 17, T3S, R6E, Pittsfield Township, Washtenaw County (FAA)

Dear Mr. Davidson:

Under the authority of Section 106 of the National Historic Preservation Act of 1966, as amended, we have reviewed the above-cited undertaking at the location noted above. Based on the information provided for our review, it is the opinion of the State Historic Preservation Officer (SHPO) that **no historic properties are affected** within the area of potential effects of this undertaking.

The views of the public are essential to informed decision making in the Section 106 process. Federal Agency Officials or their delegated authorities must plan to involve the public in a manner that reflects the nature and complexity of the undertaking, its effects on historic properties and other provisions per 36 CFR § 800.2(d). We remind you that Federal Agency Officials or their delegated authorities are required to consult with the appropriate Indian tribe and/or Tribal Historic Preservation Officer (THPO) when the undertaking may occur on or affect any historic properties on tribal lands. **In all cases**, whether the project occurs on tribal lands or not, Federal Agency Officials or their delegated authorities are also required to make a reasonable and good faith effort to identify any Indian tribes or Native Hawaiian organizations that might attach religious and cultural significance to historic properties in the area of potential effects and invite them to be consulting parties per 36 CFR § 800.2(c-f).

This letter evidences the FAA's compliance with 36 CFR § 800.4 "Identification of historic properties", and the fulfillment of the FAA's responsibility to notify the SHPO, as a consulting party in the Section 106 process, under 36 CFR § 800.4(d)(1) "No historic properties affected".

The State Historic Preservation Office is not the office of record for this undertaking. You are therefore asked to maintain a copy of this letter with your environmental review record for this undertaking. If the scope of work changes in any way, or if artifacts or bones are discovered, please notify this office immediately.

If you have any questions, please contact Brian Grennell, Environmental Review Specialist, at (517) 335-2721 or by email at ER@michigan.gov. **Please reference our project number in all communication with this office regarding this undertaking.** Thank you for this opportunity to review and comment, and for your cooperation.

Sincerely,

Martha MacFarlane Faes
Environmental Review Coordinator

RE: Section 17 Washtenaw County, Early Coordination Review of Proposed Improvements, Ann Arbor Municipal Airport, Washtenaw County, MI

Dear Ms. Lamrouex;

This letter is in response to the above referenced project.

At this time we do not have any information concerning the presence of any Indian Traditional Cultural Properties, Sacred Sites or other Significant Properties to the projected project area(s). This is not to say that such a site may not exist, just that this office does not have any available information of the area(s) at this time.

This office would be willing to assist if in the future or during the construction there is an inadvertent discovery of Native American human remains or burial objects. Feel free to call my office if you have any questions or requests at 989-775-4730.

We thank you for including this Tribe in your plans.

Sincerely,

Re: Proposed Improvement Ann Arbor Municipal Airport, Washtenaw County, MI

Dear Ms. Lamrouex:

At this time, we do not have any information concerning the presence of any Indian Traditional Cultural Properties, Sacred Sites, or Other Significant Properties in the designated area of the proposed construction site in Ann Arbor, MI. This is not to say that such site does not exist, just this office does not have any available information indicating that a site is present using our current documentation of the area. If contact could be made with the closest tribe, that being the Huron Band of Potawatomi Indians, they could possibly provide more information.

However, this office would be more then willing to assist, if in the future or during construction, there is an inadvertent discovery of Native American human remains or burial objects. I have enclosed a Site Reference Form that our office uses in the event of a discovery in order to speed the process. Please contact me if you have any further question or requests. I can be reached at (231)242-1453.

We thank you for including our tribe in your plans.

Miigwetch (thank you)

Appendix E. Field Observation Report

(June 2009)

FIELD OBSERVATION REPORT

Ann Arbor Airport, Ann Arbor, MI	6-10-09	6-19-09
SITE LOCATION	DATE	ISSUE DATE
Ann Arbor Airport Runway Expansion	50178.000	
PROJECT NAME	PROJECT NUMBER	
Carol Schulte	None	
ISSUED BY	SIGNATURE	

PARTICIPANTS	COMPANY
Carol Schulte	JJR
Tom Lee	Ann Arbor Airport

The Ann Arbor Airport was visited to investigate presence of wetlands, wildlife habitat, threatened or endangered species, and general plant communities within the limits of grading of proposed expansion areas. The site is located south of Ellsworth Road, west of State Street in Ann Arbor, MI, Washtenaw County. Tom Lee of the Airport accompanied Carol to unlock gates and allow access to the site. Pictures were taken of the site and are available for reference. Figure 1 is attached that shows airport layout as well as pertinent areas referenced in this report.

The weather during the site visit was mostly cloudy and in the high 60's.

Most of the soil south of the runway consists of Palms muck, a hydric soil. These areas contain either unmown grassy meadows or are being farmed in corn. South of the cropped area is a large forested wetland complex that was not investigated at this time. The area northwest of the runway consists of Fox and Matherton sandy loam soils and is very rocky. This area is also being farmed in corn by the same farmer.

The first area reviewed was at the east end of Runway 24 where the runway is proposed to shift southwest approximately 150'. Tom stated that generally the airport mows approximately 100' from the runway, but in this area it may be less than that because of a pledge to the local Audobon Society to keep some areas unmown for nesting meadow birds. This area was a mix of mostly wetland species and scattered upland species, including: plots of reed canary grass (*Phalaris arundinacea*), half a dozen (+/-) sedge (*Carex granularis*) plants, a few swamp milkweed (*Asclepias incarnata*), dandelion (*Taraxicum officinale*), sowthistle species (*Sonchus* sp.), buckthorn (*Rhamnus cathartica*), curly dock (*Rumex crispus*), and either goldenrod or aster species (*Solidago* or *Aster* sp.).

A County drain runs north-south on the west side of the property, then makes a turn at the end of the runway to run toward the east. The ditch is open except at the end of the runway, where it runs underground in an L-shaped culvert. The sides of the ditch on the west side are steep are approximately 6' +/- deep, but the ditch was dry in this area with only small areas of standing water on the south side. The south side ditch does not appear to have been maintained and the ditch itself is almost undefined in some areas. The standing water was tinted blue, although it was not determined what caused the tinting. The sides of the ditches contained upland weedy herbaceous species such as sweet clover (*Melilotus officinalis*), smooth brome (*Bromus inermis*), giant ragweed (*Ambrosia trifida*), Virginia creeper (*Parthenocissus quinquefolia*), lamb's quarters (*Chenopodium album*), riverbank grape (*Vitis riparia*), dame's rocket (*Hesperis matronalis*), teasel (*Dipsacus fullonum*), cow parsnip (*Heracleum maximum*), yellow goatsbeard (*Tragopogon pratensis*), yarrow (*Achillea* *millifolium*), a few reed canary grass, wheat or rye (*Triticum* or *Secale* spp), and mixed upland and wetland trees such as American elm (*Ulmus americana*), box elder (*Acer negundo*), staghorn sumac (*Rhus typhina*), Russian olive (*Eleagnus angustifolia*),buckthorn (*Rhamnus catharticus*) cottonwood (*Populus deltoides*), bur oak (*Quercus macrocarpa*), and American linden (*Tilia americana*).

The area at the end of the runway where proposed expansion will occur was investigated. This area is kept mowed and the dominant plants in this area consisted of old field weeds and grassy species, with disturbed areas of bare dirt. Plants include rough-fruited cinquefoil (*Potentilla recta*), Canada thistle (*Circium arvense*), and an unidentified grass.

Near the weather station northwest of the end of the existing runway is a gravel borrow pit, excavated, according to Tom, for a foundation for the north hangars. While this area is artificially low and the dominant tree is a large multi-trunked willow (Salix sp.), the area is not considered a wetland. The ground plain is covered with mostly burdock (*Arctium minus*) with a few dame's rocket garlic mustard (*Alliaria petiolata*), along with buckthorn, box elder, smooth brome, and one poison hemlock plant (*Conium maculatum*). Concrete rubble and other wood debris has been dumped in the low area. In an adjacent area that is higher in elevation than the borrow pit and could be a leftover spoil pile, the area is dominated by poison hemlock and stinging nettle (*Urtica dioica*), a dead ash (*Fraxinus pennsylvanica*), and several black walnuts (*Juglens nigra*).

Several examples of wildlife were observed during the short field visit; there was evidence of rodent tunneling (field mice or voles) in last year's duff at the take-off zone for Runway 24 (see Photo 2). Pheasants (*Phasianus colchicus*) were heard calling just west of the site and later in the southern portion of the site. Robins (*Turdus migratorius*), goldfinch (*Carduelis tistis*), purple martins (*Progyne subis*), and killdeer (*Charadrius viciferus*) were observed, and a mating pair of redtail hawks (*Buteo jamaicensis*) were seen flying out of the bur oak near the end of the runway. Tom stated that a pack of coyote (*Canis latrans*) have been observed on the airport property as well as wild turkeys (*Meleagris gallopavo*).

There are no regulated wetlands on the site. Although the roughly 1000 square foot area near the runway take-off zone is dominated by wetland plants and contains hydric soils, the MDEQ would likely decline jurisdiction because it is further than 500 feet from an inland lake, river, or stream, is less than 5 acres in size, and there is no surface connection with other wetlands in the area.

No threatened or endangered species or special wildlife habitat were found at the proposed impact sites.

Photo 1. Plots of reed canary grass near east end of Runway 24. 6-10-09.

Photo 2. Evidence of rodent tunneling near east end of Runway 24.

ANN ARBOR AIRPORT LAUNCHES ENVIRONMENTAL ASSESSMENT PLANNING EFFORT

ANN ARBOR, Mich., April 20, 2009 — The City of Ann Arbor is initiating the preparation of an Environmental Assessment (EA) to determine the potential impacts of lengthening the primary runway at the Ann Arbor Airport at 801 Airport Drive from 3,500' to 4,300' and a shift of the runway 150' to the southwest. The assessment results will determine potential impacts to noise levels, air quality, water quality, wetlands, floodplains, plant and wildlife, light emissions, historical and cultural resources, social, and socioeconomic factors. No runway changes will be approved until this environmental clearance process is completed.

A 12 member volunteer Citizen Advisory Council (CAC) will kick-off a series of meetings in early May as part of the assessment team. The CAC members will serve as representatives for area residents, pilots, and local municipalities. The CAC will assist with the review and discussion of the airport studies. Interested members of the public also may follow the status of the airport study via online newsletter updates, press releases, meeting notices, and by attending the public hearing. To help address questions related to the process and the potential runway improvement, two Frequently Asked Questions (FAQ) handouts have been posted on the city's airport web page. The condensed FAQ version is geared more toward non-aviation individuals. The technical FAQ version is longer and contains more detail including the specific references to various aviation regulations and practices. To sign up for periodic updates on this project, visit the airport page on the city's Web site, www.a2gov.org: select "Airport" from the "Government" drop-down menu, and then click the red envelope to subscribe.

The EA is expected to take approximately eight months to complete. The scope of the EA is defined by state and federal regulations and, upon completion, must be approved by the Michigan Department of Transportation – Bureau of Aeronautics (MDOT-Aero) and the Federal Aviation Administration. A public hearing on the findings of the EA is required by law. Public comments received will be made part of the final EA document.

The overall project consists of completing an EA documenting the potential impacts related to an 800' runway safety extension and a shift of the runway 150' to the southwest. These modifications were depicted on the Airport Layout Plan approved by city council in September 2008. The full scope of the EA will be completed by two consulting firms, JJR and URS Corporation Great Lakes. JJR, through their Ann Arbor office, will be the lead consulting firm for the EA, including the public involvement and coordination. URS Corporation, the airport's design engineer, will be preparing preliminary engineering on the runway extension and completing other technical tasks in support of the EA and JJR.

Ann Arbor has 114,000 residents, spans 27.7 square miles, and was named the No. 1 Healthiest Hometown in the U.S. by AARP The Magazine *in 2008. Other notable recognitions include: No. 27 of the top 100 U.S. cities to live in by* CNN/Money Magazine *in 2008, as well as the fourth smartest city in the U.S. by* Forbes Magazine. *The city's mission statement reads: The city of Ann Arbor is committed to providing excellent municipal services that enhance the quality of life for all through the intelligent use of resources while valuing an open environment that fosters, fair, sensitive and respectful treatment of all employees and the community we serve.*

#####

car owners relative to identification marks on railroad equipment. FRA, railroads, and the public refer to the stenciling to identify freight cars.

Annual Estimated Burden Hours: 18,750 hours.

Title: Rear-End Marking Devices.

OMB Control Number: 2130–0523.

Type of Request: Extension of a currently approved collection.

Affected Public: Railroads.

Abstract: The collection of information is set forth under 49 CFR Part 221 which requires railroads to furnish a detailed description of the type of marking device to be used for the trailing end of rear cars in order to ensure rear cars meet minimum standards for visibility and display. Railroads are required to furnish a certification that the device has been tested in accordance with current "Guidelines For Testing of Rear End Marking Devices." Additionally, railroads are required to furnish detailed test records which include the testing organizations, description of tests, number of samples tested, and the test results in order to demonstrate compliance with the performance standard.

Annual Estimated Burden Hours: 89 hours.

Title: Locomotive Certification (Noise Compliance Regulations).

OMB Control Number: 2130–0527.

Type of Request: Extension of a currently approved collection.

Affected Public: Railroads.

Abstract: Part 210 of title 49 of the United States Code of Federal Regulations (CFR) pertains to FRA's noise enforcement procedures which encompass rail yard noise source standards published by the Environmental Protection Agency (EPA). EPA has the authority to set these standards under the Noise Control Act of 1972. The information collected by FRA under Part 210 is necessary to ensure compliance with EPA noise standards for new locomotives.

Annual Estimated Burden Hours: 2,767 hours.

ADDRESSES: Send comments regarding these information collections to the Office of Information and Regulatory Affairs, Office of Management and Budget, 725 Seventeenth Street, NW., Washington, DC, 20503, *Attention:* FRA Desk Officer. Alternatively, comments may be sent via e-mail to the Office of Information and Regulatory Affairs (OIRA), Office of Management and Budget, at the following address: *oira_submissions@omb.eop.gov.*

Comments are invited on the following: Whether the proposed collections of information are necessary for the proper performance of the functions of the Department, including whether the information will have practical utility; the accuracy of the Department's estimates of the burden of the proposed information collections; ways to enhance the quality, utility, and clarity of the information to be collected; and ways to minimize the burden of the collections of information on respondents, including the use of automated collection techniques or other forms of information technology.

A comment to OMB is best assured of having its full effect if OMB receives it within 30 days of publication of this notice in the **Federal Register**.

Authority: 44 U.S.C. 3501–3520.

Issued in Washington, DC, on June 11, 2009.

Donna M. Alwine,

Acting Director, Office of Financial Management, Federal Railroad Administration.

BILLING CODE 4910–06–P

DEPARTMENT OF TRANSPORTATION

Federal Aviation Administration

FAA Notice of Intent to Prepare an Environmental Assessment; Ann Arbor Municipal Airport, Ann Arbor, MI

AGENCY: The Federal Aviation Administration, Department of Transportation.

ACTION: Notice of Intent to prepare an Environmental Assessment (EA) and conduct Citizen Advisory Meetings.

SUMMARY: The FAA has delegated selected responsibilities for compliance with the National Environmental Policy Act to the MDOT as part of the State Block Grant Program authorized under Title 49 U.S.C., Section 47128. This notice is to advise the public pursuant to the National Environmental Policy Act of 1969, as amended, (NEPA) 42 U.S.C. 4332(2)(c) that MDOT intends to prepare an EA for the proposed extension of runway 6/24 at the Ann Arbor Municipal Airport. While not required for an EA, the FAA and MDOT are issuing this Notice of Intent to facilitate public involvement. This EA will assess the potential environmental impacts resulting from the proposed extension of runway 6/24 from 3,500 feet to 4,300 feet. All reasonable alternatives will be considered including a no action alternative.

FOR FURTHER INFORMATION CONTACT: Ms. Molly Lamrouex, Environmental Specialist, Bureau of Aeronautics and Freight Services, MDOT, 2700 Port Lansing Road, Lansing, Michigan (517) 335–9866.

SUPPLEMENTARY INFORMATION: The EA will include analysis which will be used to evaluate the potential environmental impacts in the study area. During scoping, and upon publication of a draft EA and a final EA, MDOT will be coordinating with federal, state and local agencies, as well as the public, to obtain comments and suggestions regarding the EA for the proposed project. The EA will assess potential impacts and reasonable alternatives including a no action alternative pursuant to NEPA; FAA Order 1050.1E, Policies and Procedures for Considering Environmental Impacts; FAA Order 5050.4B, National Environmental Policy Act (NEPA) Implementing Instructions for Airport Actions; and the President's Council on Environmental Quality (CEQ) Regulations implementing the provisions of NEPA, and other appropriate Agency guidance.

Public Input Process: During development of the draft EA, a series of meetings to provide for public input will be held to identify potentially significant issues or impacts related to the proposed action that should be analyzed in the EA. For more information regarding the meetings for public input contact Molly Lamrouex, MDOT Bureau of Aeronautics and Freight Services, (517) 335–9866.

Issued in Romulus, Michigan, June 4, 2009.

Matthew J. Thys,

Manager, Detroit Airports District Office, Great Lakes Region.

National Highway Traffic Safety Administration

Petition for Exemption From the Vehicle Theft Prevention Standard; Nissan

AGENCY: National Highway Traffic Safety Administration (NHTSA) Department of Transportation (DOT).

ACTION: Grant of petition for exemption.

SUMMARY: This document grants in full the Nissan North America, Inc.'s (Nissan) petition for an exemption of the Murano vehicle line in accordance with 49 CFR Part 543, *Exemption from the Theft Prevention Standard.* This petition is granted because the agency has determined that the antitheft device to be placed on the line as standard equipment is likely to be as effective in

Exhibit 27

SUPPLEMENTAL REPORT
AIRPORT USER SURVEY

ANN ARBOR MUNICIPAL AIRPORT (ARB)
ANN ARBOR, MICHIGAN

December 2009

This Supplemental Report is associated with the original Airport User Survey Report for Ann Arbor Municipal Airport (ARB), dated July 2009. The information contained in this supplement provides additional details and updates to the information contained in the original report.

Additional analysis of the aircraft operational data has resulted in the generation of supplemental information, three new exhibits, and updates to the numbers of annual operations performed by category B-II critical aircraft. The following paragraphs explain in detail the information provided in the new exhibits, as well as the supplemental information and updates to the operational numbers listed in the original user survey report.

EXHIBIT No. 1: *Annual Operations Analysis by Specific Aircraft Model*

This exhibit shows annual operations at ARB by specific aircraft model, rather than only by their FAA aircraft classification as shown in the original user survey report. The various aircraft models are listed in three separate tables, based upon groupings of their FAA classifications (B-II, C-I, and C-II).

Supplemental data associated with annual operations by the Beechcraft King Air C90 has been included in the B-II category table of this exhibit. Operations by this particular model of aircraft were not included in the original July 2009 Airport User Survey Report.

EXHIBIT No. 2: *Origin / Destination Analysis by State*

Exhibit No. 2 shows the results of an origin and destination analysis of aircraft operations conducted at ARB, based on examination of the FlightAware database from survey year 2007. Although 274 of the operations had aircraft model and ownership information blocked from the database at the aircraft owner's request, the origin and destination cities of each flight were still included.

The first column of the table shown in this exhibit lists 31 states (and Washington DC) from which operations into ARB originated, or operations out of ARB were going to as a destination. The second column lists operations attributed to each state by the 274 total operations with blocked aircraft and ownership records. The third and fourth columns list operations attributed to each state by B-II Small and B-II Large category aircraft. The last column lists the total number of operations attributed to each state.

The numbers of operations associated with each state are from the FlightAware Instrument Flight Rule (IFR) flight plan database only, and do not include records of all itinerant operations between ARB and other states. Nonetheless, the numbers shown in this exhibit confirm that in 2007, flight operations were conducted between ARB and at least 31 other states (approximately 63% of the continental US). Also, approximately 67% of the IFR flight records for the category B-II critical aircraft were between ARB and out-of-state locations. These factors confirm that there is a significant amount of flight operations being conducted at ARB that are either going to, or coming from, distant locations in other states.

EXHIBIT No. 3: *Small 10-Seat Aircraft Analysis*

The table in this exhibit lists *Small* aircraft models (less than or equal to 12,500 lbs. maximum certificated takeoff weight) that have 10 or more passenger seats, and that conducted operations at ARB in survey year 2007. The numbers of annual operations listed in the table are from the FlightAware IFR flight plan database only, and do not include records of all operations by aircraft of this type. The FlightAware records show that there were 425 annual operations by Small 10-seat or higher aircraft.

Exhibit No. 3 also shows that there were 211 annual operations by *Large* category (greater than 12,500 lbs. maximum certificated takeoff weight) B-II aircraft from the Based Aircraft data source and another 85 annual operations by Large category B-II aircraft from the FlightAware data source. The number of annual operations performed by the Small 10-seat or higher aircraft and the Large category aircraft combined is shown as 721.

The operational numbers listed in Exhibit No. 3 do not include blocked FlightAware operations, Visual Flight Rule (VFR) operations, or operations logged by pilots on the Fixed Base Operator (FBO) airport registers. Although the information shown is only a partial representation of all applicable aircraft, the 721 annual operations that were substantiated significantly confirm that Figure 2-2 in FAA Advisory Circular 150/5325-4B is the appropriate chart to reference in the determination of the FAA-recommended runway length of 4,200 feet at ARB.

UPDATED BASED AIRCRAFT ANALYSIS:

The Based Aircraft Analysis of the original user survey report listed 200 estimated annual operations by AvFuel's B-II Large category aircraft (see page 3 of the original report). AvFuel's Chief Pilot has since confirmed in writing that the actual number of operations by their Cessna Citation XL 560 aircraft at ARB over the past three calendar years has been 224 operations in 2006, 211 operations in 2007, and 223 operations in 2008.

In order to maintain consistency with the other survey year 2007 operational records analyzed, Exhibit No. 1 of this Supplemental Report shows the 211 actual annual operations by this aircraft in the "Based Aircraft Data Source" column of the category B-II table, instead of the original estimate of 200.

UPDATED ITINERANT AIRCRAFT ANALYSIS: (FBO Data Sources)

Itinerant (visiting) aircraft operational data that was evaluated as part of the original user survey analysis was obtained from the pilot registration logs (airport registers) of two of the airport's FBOs - Solo Aviation and Ann Arbor Aviation Center. Data was examined for a six-month survey time frame, and cross-checked against FlightAware records in order to prevent counting the same aircraft twice. Any operations that were already included in the FlightAware records were not included in the operational totals that were generated from the FBO records.

The FBO records provided 40 additional operations by B-II and greater category aircraft (32 by category B-II aircraft, 6 by category C-I aircraft, and 2 by category C-II aircraft). Since this data was based on a six-month time frame instead of the full calendar year 2007, these 40 actual operations were prorated into an estimated equivalent annual rate of 80 operations. The additional 40 estimated operations were the only operations in the original user survey analysis that were obtained by prorating actual partial-year data into an estimated equivalent annual rate.

As part of the supplemental analysis, estimated operations that were originally generated as a result of prorating partial-year data were not considered in the determination of the annual operations at ARB. This eliminates the potential effect of seasonal variation in flight activity levels negatively influencing annual operational estimates. Only the 40 actual operations that were documented by the FBOs as having occurred within the six-month survey period were counted as valid operations, since they did in fact occur in 2007. No operations were attributed to the remaining six months.

Exhibit No. 1 of this supplemental report shows only the 40 actual documented operations (32 by category B-II aircraft, 6 by category C-I aircraft, and 2 by category C-II aircraft) in the column that is labeled "2 FBO Register Data Sources".

UPDATED FLIGHTAWARE DATABASE ANALYSIS:

The FlightAware database analysis that was performed for the original July 2009 Airport User Survey Report resulted in the determination of 265 actual annual operations by B-II Small aircraft, and another 85 actual annual operations by B-II Large aircraft (see page 6 of the original report). However, the resulting numbers did not include operations by the Beechcraft King Air C90 model.

The King Air C90 is a B-II Small category aircraft, with a wingspan of 50'3". Earlier versions of the King Air 90 models (A90 and B90) have wingspans of less than 49', and are therefore category B-I Small aircraft. Since the FlightAware records that were originally analyzed for ARB did not include information which identified the specific model of each King Air 90 operation, no operations by King Air 90s were included in the original user survey analysis and report.

Although the FlightAware records do not provide information regarding the specific model of each King Air 90 operation listed, they do provide the aircraft registration N-number of each aircraft. By entering the N-number into the computerized FAA aircraft registration database, the specific model of each King Air 90 operation was able to be determined. A total of 157 operations by the B-II Small category King Air C90 model have been identified, out of 220 operations by King Air 90 models of all types.

Exhibit No. 1 of this supplemental report shows the 157 King Air C90 operations included in the "Flight Aware Data Source" column of the category B-II table. By adding these operations to the 265 operations by B-II Small aircraft and 85 operations by B-II Large aircraft that were previously identified in the original user survey report, the updated total number of actual annual operations by B-II category aircraft obtained from the FlightAware data source is 507.

The FlightAware database also confirmed usage of the airport by many large corporations, in addition to AvFuel, which is the only one actually based at ARB. Some of the other corporate users of ARB include Synergy International, Wells Fargo, Polaris Industries, Bombardier Aerospace, Avis Industrial Corporation, Thumb Energy, and NetJets. NetJets provides on-demand air charter services and corporate aircraft fractional ownership opportunities to a large number of other corporations that are located throughout the country.

AIRCRAFT OPERATIONAL FORECASTS:

Year 2007 was the onset year of the current planning activities associated with the potential extension of Runway 6/24. At that time, the airport manager and FBOs were requested to collect based and itinerant aircraft operational data over the course of year 2007 for the purpose of determining project justification. This data was reviewed during the user survey analysis, which was conducted in early 2009.

FlightAware records for any given year are not published until that particular calendar year has ended, and all operations that took place during the course of that year counted. Since the user survey analysis was conducted in early 2009, the most current operational records available at the time from FlightAware were associated with calendar year 2008. Although year 2008 records were available, year 2007 records from FlightAware were used in the user survey analytical process. This was due to the importance of maintaining consistency of year of operational records in the analysis, and not combining operational data collected by the airport manager and FBOs over year 2007 with the more recent FlightAware records from year 2008. The FlightAware records, airport manager records, and FBO records from calendar year 2007 that were used in the user survey analysis were all only one-year old at the time, and still considered valid for use in determining project justification.

The FAA Terminal Area Forecast (TAF) does project a short-term approximate 22% decrease in total annual operations at ARB from user survey year 2007 through year 2009 (from 72,895 actual in 2007 to 56,956 estimated for 2009). However, beginning in year 2010, the TAF projects continuously increasing annual operations at ARB, from the year 2009 low-point through year 2030. Itinerant annual operations are even projected to surpass survey year 2007 levels prior to the end of the 2030 forecast period.

Even if the worst case short-term projected 22% decrease in total annual operations is applied to the user survey results, there is still significant justification for the runway extension. The user survey report documents a total of 750 actual annual operations by B-II category critical aircraft that justify the runway extension. A 22% decrease in this number is 585 - still well above the FAA's substantial use threshold of 500. And again, beginning in 2010, operations at ARB are projected by the FAA to begin increasing every single year from that point forward, through year 2030.

Forecasts from the MDOT Michigan Airport System Plan (MASP 2008) also project increasing itinerant and total operations at ARB from years 2010 through 2030. The MDOT forecasts further substantiate the mid-term and long-term FAA projections of a rebound in current operational activity at ARB to survey year 2007 levels.

AvFuel Corporation, which bases a B-II Large category Citation 560 Excel jet at ARB, has confirmed that their operations at ARB actually increased from 211 operations in 2007 to 223 operations in 2008. Their Chief Pilot estimates that their future operational levels could potentially increase to 350 to 450 operations per year at ARB.

The FAA TAF forecast, MDOT MASP forecast, and AvFuel's operational forecasts all provide support to the fact that survey year 2007 operational data is a very pertinent representation of estimated future operational levels at ARB.

SUMMARY:

The supplemental analysis that was conducted after publication of the July 2009 Airport User Survey Report has resulted in additional justification in support of extension of Runway 6/24 to 4,300' in length.

Further analysis of the FlightAware IFR flight plan database has confirmed 507 actual operations at ARB in survey year 2007 by B-II category aircraft. This number does not include operations in the FlightAware records with aircraft information blocked at the owner's request, or VFR operations that were conducted without flight plans. Judging by the high number of out-of-state origin and destination locations of operations listed in the blocked category (see Exhibit No. 2), it is very likely that many of the associated aircraft were of the B-II or greater categories. Therefore, actual operations at ARB by aircraft of these categories are likely considerably higher than the 507 substantiated operations obtained from the FlightAware database.

The 507 actual operations by B-II category aircraft that were obtained from the FlightAware database also do not include operations conducted by AvFuel's based Cessna Citation XL 560, or operations obtained from the two FBO airport registers. AvFuel has confirmed 211 actual operations at ARB in 2007 with their B-II category aircraft, and data provided by the FBOs has confirmed 32 actual operations in 2007 by B-II category aircraft.

In summary, the supplemental analysis of this user survey has confirmed a total of 750 actual annual operations at ARB by category B-II aircraft. FlightAware records also confirmed that operations by aircraft in this critical aircraft category were performed by many large corporations, some of which are listed on page 4 of this report.

CONCLUSION:

In the majority of airport user survey processes, determinations and recommendations are issued based on analysis of estimated annual operations obtained from various airport users. In conducting the user survey at ARB, the analysis focused on evaluation of actual annual operations performed at the airport. This is obviously a much more accurate method of calculating the total number of annual operations associated with the determination of the critical aircraft and Airport Reference Code. It also eliminates the possibility of an airport user inflating their estimated operational numbers, in the hopes of obtaining a longer runway that is not truly justified.

While the numbers listed in this report do not include every operation that occurred at ARB in survey year 2007 with B-II category aircraft, they do confirm substantial usage of the airport by aircraft of this critical aircraft category. The Origin/Destination Analysis has shown a significant number of operations between ARB and distant out-of-state locations, which is a very good indicator of corporate activity associated with interstate commerce, as opposed to pleasure flying by general aviation pilots. FlightAware records also confirmed usage of the airport by many large corporations.

The information contained in this Supplemental Report provides additional justification in support of the findings and recommendations of the original July 2009 Airport User Survey Report. The user survey analysis has shown that justification for the proposed extension of primary Runway 6/24 to 4,300-feet has been confirmed, and the proposed project has been determined to be eligible to receive state and federal funding.

Although justification for the proposed project has been substantiated according to current MDOT and FAA standards associated with runway length recommendations, neither agency requires that the runway be extended. It is ultimately – and entirely – the decision of the city of Ann Arbor whether or not to proceed with the development of the project.

CRITICAL AIRCRAFT CATEGORY DETERMINATION: B-II (Based on 750 Total Annual Operations by Aircraft of this Category)

NOTE: The annual operations listed in the above tables are ACTUAL documented operations from calendar year 2007.
The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.
Operations recorded by the FBOs and listed above represent only a partial-year (six-month) time frame.

A total of 274 operations in the FlightAware database had aircraft model and ownership information blocked at the owner's request.
As a result, their operational numbers are NOT included in the information shown above.
Judging by the high number of out-of-state origin and destination locations of aircraft in the blocked category (see Exhibit No. 2), it is very likely that many of the associated aircraft were of the B-II and greater categories.
Therefore, actual operations at ARB by aircraft of these categories are likely considerably higher than the numbers shown above.

EXHIBIT NO. 2 **ORIGIN / DESTINATION ANALYSIS BY STATE**

Origin / Destination Analysis of IFR Aircraft Operations Between ARB and Other States
(Records from FlightAware 2007 Database)

	STATE	Aircraft Type & Category Blocked	B-II Small Category	B-II Large Category	Totals by State
1	Alabama	0	1	0	1
2	Arizona	1	0	0	1
3	Arkansas	2	1	0	3
4	Connecticut	5	2	0	7
5	Florida	29	3	3	35
6	Georgia	5	6	12	23
7	Illinois	25	64	5	94
8	Indiana	6	21	1	28
9	Iowa	1	20	3	24
10	Kansas	3	0	0	3
11	Kentucky	2	13	0	15
12	Maine	2	0	0	2
13	Maryland	1	3	7	11
14	Massachusetts	5	0	1	6
15	**Michigan**	**79**	**162**	**20**	**261**
16	Minnesota	2	3	2	7
17	Missouri	0	5	0	5
18	Nebraska	3	0	1	4
19	New Hampshire	1	2	0	3
20	New Jersey	9	2	4	15
21	New York	6	5	1	12
22	North Carolina	4	1	1	6
23	Ohio	16	38	13	67
24	Pennsylvania	14	23	4	41
25	South Carolina	0	4	0	4
26	South Dakota	4	18	0	22
27	Tennessee	2	5	0	7
28	Texas	30	0	0	30
29	Virginia	1	3	0	4
30	Washington DC	5	1	2	8
31	West Virginia	1	7	0	8
32	Wisconsin	10	9	4	23
	No Record	0	0	1	1
	Totals by Category	**274**	**422**	**85**	**781**

IFR Aircraft Operation Totals by Category:

Within Michigan	79	162	20	261
Outside of Michigan	195	260	64	519
No Record	0	0	1	1

NOTE: The numbers of operations listed above are ACTUAL documented operations from calendar year 2007. The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.

The numbers shown above are from the FlightAware IFR Flight Plan Database only, and do NOT include records of all itinerant operations between ARB and other states. Nonetheless, the numbers shown above confirm that in 2007, flight operations were conducted between ARB and at least 31 other states and Washington DC (approx 63% of the continental US). Approximately 67% of these IFR flight records were between ARB and out-of-state locations.

EXHIBIT NO. 3 SMALL 10-SEAT AIRCRAFT ANALYSIS

Small Airplanes Having 10 or More Passenger Seats
(Records from FlightAware 2007 Database)

Aircraft Model	FAA Approach Category	FAA Design Group	FAA Weight Class	Seating	Maximum Takeoff Weight	Aircraft Engine Type	Annual Operations
Cessna Caravan 208	A	II	Small	10+	<12,500	Single-Eng	11
Swearingen Merlin III	B	I	Small	10+	<12,500	Multi-Eng	3
Beechcraft King Air C90	B	II	Small	10+	<12,500	Multi-Eng	157
Beechcraft King Air 100	B	II	Small	10+	<12,500	Multi-Eng	39
Beechcraft King Air 200	B	II	Small	10+	<12,500	Multi-Eng	215

Total Small 10-Seat Aircraft Annual Operations **425**

Total B-II Large Category Aircraft Annual Operations

Based Aircraft Data Source (B-II Large): **211**
FlightAware Data Source (B-II Large): **85**

Grand Total Annual Operations at ARB Applicable to Figure 2-2 in FAA Advisory Circular 150/5325-4B: **721**

NOTE: The annual operations listed above are ACTUAL documented operations from canendar year 2007.
The numbers do NOT include any ESTIMATED operations obtained through proration of partial-year data, or other methods.

The numbers shown in the table above are from the FlightAware IFR Flight Plan Database only, and do NOT include records of all small aircraft operations at ARB with 10-seat or greater aircraft models. Nonetheless, the above analysis confirms that Figure 2-2 in FAA AC 150/5325-4B is the appropriate chart to reference in the determination of the FAA-recommended runway length for Ann Arbor Municipal Airport.

2008 DRINKING WATER QUALITY REPORT

Ann Arbor Public Services 2008
Annual Report on Drinking Water

Construction of Barton Dam - 1927

http://www.a2gov.org/government/publicservices

The staff of Ann Arbor Public Services is strongly committed to bringing you the best drinking water possible. We take pride in not only meeting all federal and state drinking water regulations, but in reaching higher goals. We participate in voluntary programs which improve our organization and establish more stringent water quality goals. Our monitoring programs far exceed those required to assure the quality of your drinking water. The USEPA requires water utilities provide the following information to their customers as part of their Annual Water Quality Report. This information is generic and may or may not apply to Ann Arbor drinking water. If you have any questions on this language, you may contact the USEPA Safe Drinking Water Hotline at (800) 426-4791.

Water Supply and Treatment

The Ann Arbor water supply is comprised of both surface and ground water sources. About 85% of the water supply comes from the Huron River. The remaining 15% comes from multiple wells located south of Ann Arbor. The water from both the sources is blended at the water treatment plant. Since we use a surface water supply, (Huron River water), the United States Environmental Protection Agency (USEPA) and the Michigan Department of Environmental Quality (MDEQ) regulations require it to be treated, filtered and disinfected to ensure that any harmful substances are removed. When treatment is complete, the water is pumped to homes, schools and businesses in Ann Arbor as well as to Ann Arbor and Scio townships for resale to their customers.

The following is the official USEPA language on Cryptosporidium: *Cryptosporidium is a protozoan parasite that is too small to be seen without a microscope. It is sometimes found in some surface waters, especially when the waters contain a high amount of fecal waste from run-off or other activities. Those who are infected with this parasite can experience gastrointestinal illness.*

USEPA and the Centers for Disease Control have published guidelines on ways to reduce the risk of Cryptosporidium infection. The guidelines are available from the Safe Drinking Water Hotline at (800) 426-4791.

Samples have been collected from the source and no detectable levels of Cryptosporidium were found.

The following is the official USEPA language on contaminants that may be in untreated water: *The sources of drinking water - both tap water and bottled water include: rivers, lakes, streams, ponds, reservoirs, springs and wells. As water travels over the surface of the land and through the ground, it dissolves naturally occurring minerals and can pick up substances resulting from the presence of animals or from human activity.*

Contaminants that might be expected to be in source water - untreated water - include: microbial contaminants, such as viruses and bacteria; inorganic contaminants, such as salts and metals; pesticides and herbicides; organic chemical contaminants; including synthetic and volatile organic chemicals; and radioactive contaminants, which can be naturally occurring.

In order to ensure tap water is safe to drink, the EPA prescribes regulations which limit the amount of certain contaminants in water provided by public water systems. Food and Drug Administration regulations establish limits for contaminants in bottled water, which must provide the same protection for public health.

Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the EPA Safe Drinking Water Hotline at (800) 426-4791.

The following is the official USEPA language on low resistance to infection: *Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-compromised persons such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly and infants can be particularly at risk from infections. These people should seek advice from their health care providers. Environmental Protection Agency / Centers for Disease Control guidelines on appropriate means to lessen the risk of infection from Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline at (800) 426-4791.*

Spotlight on Water Emergencies

Q: How will I know if my water isn't safe to drink?
A: If there is a chance your water may not be safe to drink, you will be notified by newspaper, mail, radio, TV, or hand-delivery. The notice will describe any precautions you need to take, such as boiling your water. There are 4 possible types of emergency notifications: Boil Water Advisory, Boil Water Notice, Do Not Drink Notice and Do Not Use Notice.

To receive free emergency notifications from the City of Ann Arbor, sign up for the free CodeRed phone alert service, as posted on the city's front Web page at www.a2gov.org. You can also sign up for emergency e-mail updates through the "red envelope" option on the city's front Web page.

Q: What is a Boil Water Advisory? Is it the same as a Boil Water Notice?
A: A Boil Water Advisory is a public statement advising customers to boil tap water before consuming it. Advisories are issued when an event occurs that may cause the water distribution system to become contaminated, such as a loss of pressure from a water main break or back siphonage event. An advisory does not mean that the water is contaminated, but that there is a chance contamination has occurred. Customers should take appropriate precautions until water quality can be determined. An advisory is different from a Boil Water Notice, which is issued when contamination is confirmed in the water system.

Q: What should I do during a Boil Water Advisory or Notice?
A: You should boil tap water vigorously for at least one minute (the minute starts when the water begins to bubble). Wait for the water to cool before using it. This includes water used for brushing teeth, making ice, washing raw foods, preparation of drinks, and water for pets. If preferred. customers can use bottled water. You may store boiled water in the refrigerator in a clean container. Boiling removes harmful bacteria in the water that may cause illness. You should throw away ice made during the time the advisory or notice was issued, as freezing does not kill bacteria.

You should flush the piping inside your home once the advisory or notice has been lifted. Follow these guidelines for flushing:

" Run all cold water faucets in your home for one minute
" To flush automatic ice makers, make and discard several batches of ice
" Run drinking water fountains for one minute

Q: Do I still need to boil my water if I have a filter system on my faucet or refrigerator?
A: Most point-of-use filters are designed to improve the taste and odor of water and will not remove harmful bacteria. Thus, it is recommend that you boil your water or use bottled water even if you have a filtering system. You can learn about the capability of your filter by contacting the manufacturer or NSF International, an independent testing group located in Ann Arbor (734-769-8010).

Q: Is the water safe for washing dishes, laundry , and bathing during a Boil Water Advisory or Notice?
A: The water is safe for washing dishes, but you should use hot, soapy water (you may add one tablespoon of bleach per gallon as a precaution) and rinse dishes in boiled water. There are no restrictions on doing laundry or bathing.

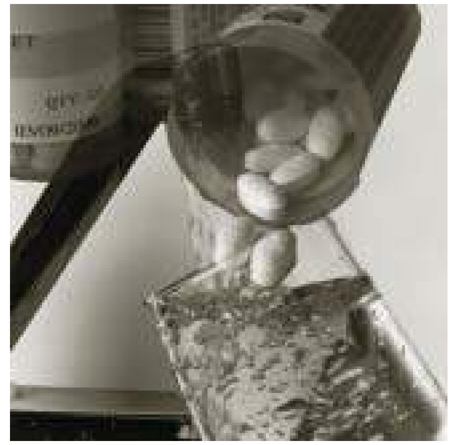
Q: How long must a Boil Water Advisory or Notice be in effect?
A: An advisory or notice will remain in effect until test samples show the water is safe to drink. Testing for bacteria requires 24 hours to complete. As a result, advisories and notices will be in effect for at least 24 hours.

Q: What are total coliform bacteria?
A: Total coliform bacteria are a collection of microorganisms that are naturally present in the environment. Coliform bacteria are found in soil, water and the intestines of warm blooded animals. Coliform bacteria are not harmful themselves, but are used as an indicator that other, potential disease causing organisms may be present. The water treatment process effectively kills coliform bacteria. However, events such as a water main break or a loss of pressure in the water distribution system may allow these bacteria to enter water lines through cracks in pipes or back-siphoning from a residential plumbing system. Boiling water vigorously for one minute will kill these bacteria and make water safe to drink.

Q: What is a Do Not Drink Notice?
A: A Do Not Drink Notice will be issued when the water contains a chemical contaminant that cannot be removed by boiling. In this case, bottled water should be used for drinking or cooking.

Q: What is a Do Not Use Notice?
A: A Do Not Use Notice will be issued if there is a contaminant in the water that may be inhaled or otherwise harmful on contact. In this case, bottled water should be used for all water consumption, including bathing, cooking and laundry.

Pharmaceuticals in Drinking Water?



Q: Has the city of Ann Arbor ever tested our water for pharmaceuticals and personal care products (PPCP)?

A: Yes. Through grants from the Michigan Department of Environmental Quality (MDEQ) in 2004 and 2005, the City completed studies to determine if these contaminants were present in our water. We tested both our source water and finished drinking water for the presence of 33 pharmaceutical and personal care products (PPCP). Of the 33 contaminants, 12 were detected in finished water. All results were in the parts per trillion range.

In 2008, the City of Ann Arbor tested the finished drinking for 8 endocrine disrupting compounds, including Bisphenol A (BPA). None of these compounds were found to be present in the drinking water.

To read the City's PPCP study reports or to see the 2008 endocrine disrupting chemical test results, please visit our webpage:
http://www.a2gov.org/government/publicservices/water_treatment/Pages/default.aspx

To help prevent PPCPs from entering the drinking water supply, never flush any drugs down the toilet. Take unused over the counter and prescription medications back to participating pharmacies for disposal, or wrap medication in in plasitc bags, seal with duct tape and then dispose in the trash. For information about proper disposal, visit www.dontflushdrugs.com

Source Water Assessment and Protection Plan

The City of Ann Arbor has completed a Source Water Assessment and Protection Plan. This plan determines the protection areas for all of our sources of supply, assesses the potential for contamination and develops plans for improving protection of those areas. The assessments for both the river and groundwater supplies included determining the susceptibility, or relative potential of contamination impacting each source of supply. A six-tiered scale was used to rate the potential for contamination. The scale ranges from “very low” to “high”.. The susceptibility rating is based on the geologic sensitivity and the number and types of potential contaminant sources located within our source water protection areas. The susceptibility of the Huron River supply was rated “high” and the wells were rated “moderate”.

New Process at the Ann Arbor Water Treatment Plant

On June 8, 2001, the United States Environmental Protection Agency (USEPA) published the Filter Backwash Recycle Rule (FBRR). This rule regulates the point at which water can be reused and added to the treatment process at water treatment plants. The intent of this rule is to reduce the potential of passing Cryptosporidium oocysts and other biological pathogens such as bacteria and viruses into the finished drinking water.

The City of Ann Arbor uses filters in its treatment process to remove micron size contaminants from its raw water sources. These filters must be cleaned every few days by backwashing-or running water through the filters in reverse at a high rate to remove embedded particles and biological pathogens. This backwash water contains concentrated contaminants that, prior to this rule and the subsequent improvements made at the Ann Arbor Water Treatment Plant, were recycled to the front end of the plant and mixed with the water coming from the city's wells and the Huron River. This water is then treated with the raw water prior to distribution with the treated drinking water. Because the backwashing process is at such a high rate, this causes surges in the flow through the plant when filters are washed. These surges can create a situation of inconsistencies in the treatment process and potentially lead to contaminants making it through the treatment process into the finished drinking water.

The FBRR rule required Ann Arbor to add a new process to the Water Treatment Plant to address this surging of flow caused by backwashing filters. The city was required to add a 750,000 gallon concrete tank and associated pump station to hold the backwash water before it is pumped back into the plant for treatment at a low controlled rate. This new process was completed and put on line in the end of 2008. This process has resulted in more reliable treatment of the city's drinking water and better water quality.

Water Quality Test Results

The following regulated substances were detected in some samples.

Please note that some substances, such as monochloramine and fluoride, are added to the water to improve health. All the detected substances are well within stringent Federal and State limits.

Definitions: The following tables contain scientific terms and measures, some of which may require explanation.

- **Maximum Contaminant Level (MCL):** The highest level of a contaminant that is allowed in drinking water. MCL's are set as close to the Maximum Contaminant Level Goal as feasible using the best available treatment technology.
- **Maximum Contaminant Level Goal (MCLG):** The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLG's allow for a margin of safety.
- **mg/l:** milligrams per liter or parts per million - or one ounce in 7,350 gallons of water
- **µg/l:** micrograms per liter or parts per billion - or one ounce in 7,350,000 gallons of water
- **na:** not applicable
- **Avg:** Regulatory compliance with some MCLs are based on running annual average of monthly or quarterly samples.
- **ND:** Non detectable

Regulated at the Water Treatment Plant

Regulated Substance	Highest Level Detected	Range of Individual Samples	MCL	MCLG	Source of Contamination
Fluoride	1.26 mg/l	ND – 1.26 mg/l	4 mg/l	4 mg/l	Added to water to promote strong teeth. Erosion of natural deposits. Discharge from fertilizer factories.
Nitrate	0.5 mg/l	0.34 – 0.5 mg/l	10 mg/l	10 mg/l	Run-off from fertilizer use. Leaching from septic tanks and sewage. Erosion of natural deposits.
Bromate	2 µg/l avg	ND – 6 µg/l	10 µg/l	0 µg/l	By-product of ozone disinfection of drinking water.
Total Organic Carbon	30.1% Removal[1]	30.1–72.6% Removal	<25% Removal	na	Naturally occurring
Barium	19 µg/l	na	2000 µg/l	2000 µg/l	Erosion of natural deposits
Chromium	2.1 µg/l	na	100 µg/l	100 µg/l	Erosion of natural deposits

[1] Poorest removal corresponds to highest concentration

Monochloramine - Regulated at the Distribution System

Definitions:

- **Maximum Residual Disinfectant Level (MRDL):** The highest level of disinfectant allowed in drinking water.
- **Maximum Residual Disinfectant Level Goal (MRDLG):** The level of disinfectant in drinking water below which there is no known or expected risk to health. MRDLG's allow for a margin of safety.

Regulated Substance	Highest Level Detected	Range of Individual Samples	MRDL	MRDLG	Source of Contamination
Monochloramine	2.7 mg/l avg	2.4 –2.9 mg/l	4 mg/l	4 mg/l	Disinfectant added at Water Plant

Turbidity - Regulated at the Water Treatment Plant

Definitions:

- **Turbidity:** A measure of cloudiness of water. The Ann Arbor Water Treatment staff monitors it because it is a good indicator of the effectiveness of the filtration system. Turbidity must be less than 0.3 NTU in at least 95% of the measurements taken throughout each month. It must never exceed 1.0 NTU.
- **Nephelometric Turbidity Unit (NTU):** A measure of light scattered from particles in the water.
- **Treatment Technique (TT):** A process intended to reduce the level of a contaminant in drinking water.

Regulated Element	95th Percentile TT achieved (max)	95th Percentile TT required	95th Percentile TT voluntary goal	Lowest % of samples within requirements	Single highest measurement	Source of Contamination
Turbidity	0.17 NTU	0.3 NTU	0.1 NTU	0	0.35 NTU	Soil Runoff

Water Quality Test Results

The following regulated substances were detected in some samples.

Copper and Lead - Regulated at the Customer's Tap - All samples collected and analyzed were well within the strict Federal and State limits. The data is from the 2008 testing conducted in accordance with regulations. If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Ann Arbor is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting for several hours, you can minimize the potential for lead exposure by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at: http://www.epa.gov/safewater/lead. The City of Ann Arbor sampled 54 homes and 2 of these homes exceeded the action level for lead.

Definitions:

- **Action Level (AL):** The concentration of a contaminant which, if exceeded, triggers treatment or other requirements which a water system must follow.
- **Action Level Goal (ALG):** The level of a contaminant in drinking water below which there is no known or expected risk to health. ALG's allow for a margin of safety.

Regulated Substance	Detection Level at the 96th Percentile	AL	ALG	Source of Contamination
Lead - 2008 Customers plumbing	8 µg/l	15 µg/l	0 µg/l	Corrosion of household plumbing systems Erosion of natural deposits

Regulated in the Distribution System

Regulated Substance	Highest Level Detected	Range of Individual Samples	MCL	MCLG	Source of Contamination
Total Coliform	Detected in 1.43% of all samples taken in August	ND – 1.43%	Detected in not more than 5% of samples taken monthly	0	Naturally occurring in the environment
Total Trihalomethanes	[1] 17.8 µg/l avg	0.76– 6.8 µg/l	80 µg/l	0 µg/l	By-product of drinking water disinfection
Total Haloacetic Acids	[1] 11 µg/l avg	1.1 – 9 µg/l	60 µg/l	0 µg/l	By-product of drinking water disinfection

[1] Highest running annual average of last four quarters include sample results from 2007

These tests also showed the following characteristics in our water. Federal and State standards have yet to be established and all results are within limits accepted by most public health officials.

Non-regulated Substance	Average	Range of Individual Samples	Source of Contamination
Hardness	142 mg/l	99 – 200 mg/l	Naturally occurring minerals; controlled by water treatment process
pH	9.3	9.1 – 9.5	Controlled by water treatment process
Aldehydes	8 µg/l	ND – 33 µg/l	By-product of drinking water ozonation
1,4-Dioxane	ND	ND	Groundwater contamination from manufacturing process and landfills
Perchlorate	0.08 µg/l	na	Groundwater contamination from manufacturing process
Sodium	55 mg/l	42–72 mg/l	Naturally occurring minerals; run-off of road salt into surface water; caustic soda used in water treatment process; bleach used in water treatment process

Notice of Violations

We are required to monitor your drinking water for specific contaminants on a regular basis as required by USEPA and MDEQ. In addition to all required testing, we voluntarily monitor more frequently and for many additional potential contaminants. Results of regular monitoring are an indicator of whether or not our drinking water meets health standards. During 2008 we did not monitor or test for endothall during the required sampling period. Additionally, we did not monitor our wells in the first quarter for Volatile Organic chemicals (VOCs) and we also failed to monitor one of the four wells in the third quarter for VOCs. These violations **do not** pose a threat to the quality of the city's water. The table below lists the contaminants we did not properly test for during 2008:

Contaminant	Required sampling frequency	Number of taken samples	When all samples should have been taken	Date sample was taken
Endothall	1 / year	0	4/1/2008 - 9/30/2008	11/17/2008
VOCs	4 / quarter	0	1/1/2008 - 3/31/08	4/18/2008
VOCs	4 / quarter	3	7/31/2008 - 9/30/08	10/16/2008

On January 8, 2008, one of the 26 water filters unexpectedly discharged water with high turbidity into one of the water treatment plant's two filtered water chambers. Turbidity standards were exceeded at the water treatment plant for 42 minutes. Bacteriological testing of water samples indicated that the safety of the city's drinking water was not jeopardized during the event. A notice of the incidence was mailed to customers on January 28, 2008.

Additional Information & Contacts

The City of Ann Arbor Water Treatment Plant conducts extensive routine monitoring of water quality. Our testing program far exceeds current regulatory requirements and we are vigilant against potential threats to our water system.

The Public Services Area Administrator attends the Ann Arbor City Council meetings to provide information on the water system. All Council general sessions, the first and third Monday of each month, are open to the public. Unless announced otherwise, the meetings are at 7:00 PM in Council Chambers at City Hall, 100 North Fifth Avenue. Council meetings are also broadcast on cable channel 16, CTN. In addition, targeted public meetings are periodically held to discuss improvements and to listen to our citizens' and customers' concerns.

Commission OKs FY 2013 Parks Budget

Also: Windemere tennis court problems; drain project at Veterans

BY MARY MORGAN APRIL 27, 2012 at 8 am

Ann Arbor park advisory commission meeting (April 17, 2012): The action items at this month's PAC meeting focused on the upcoming fiscal year, with parks-related budget recommendations for July 1, 2012 through June 30, 2013. Sam Offen, who chairs PAC's budget and finance committee, observed that the FY 2013 budget is in better shape than in recent years.

At left is city councilmember Christopher Taylor (Ward 3), who also serves as an ex officio member of the Ann Arbor park advisory commission. To the right is Sam Offen, chair of PAC's budget and finance committee. (Photos by the writer.)

This is the second year of a two-year budget cycle, and commissioners had recommended approval of budgets for both years at their April 2011 meeting. The recent recommendations for FY 2013 include: (1) increasing the frequency of the mowing cycle from every 19 days to every 14 days; (2) increasing seasonal staffing between April 15–October 15 to maintain active recreation areas better; (3) establishing three seasonal park steward/supervisor positions to improve park maintenance and enforcement; and (4) increasing seasonal staffing at the ice arenas to improve facility cleanliness.

Fee increases at several parks and rec facilities are also part of the budget recommendations, but most have already been implemented in the current fiscal year.

The April 17 meeting included a public hearing on the renewal of the city's park maintenance and capital improvements millage, which will likely be on the November 2012 ballot. No one spoke at the hearing. In general, "there seems to be a great deal of relative silence" about the millage, parks and rec manager Colin Smith told commissioners. Few people have attended the recent public forums held by parks staff. The final forum is set for Thursday, April 26 from 6:30-7:30 p.m. at the Ann Arbor District Library's Traverwood branch, 3333 Traverwood Drive.

Parks staff gave an update on deteriorating conditions at Windemere Park's two tennis courts, and provided an initial estimate on costs to replace one or both courts at that location. No formal recommendation has been made, but options include moving the courts to another park. Commissioners discussed the need to assess the distribution and conditions of all of the city's public courts – including ones in the public school system – as well as their overall usage, to get a better idea of where the greatest needs are.

Another update came from an engineer at the Washtenaw County water resources commissioner's office, who described a drain replacement project that will affect Veterans Memorial Park later this year. Also related to Veterans Memorial, the request for proposals (RFP) for a skatepark there has been issued. [.pdf of skatepark RFP] The goal is to solicit proposals for a consultant to handle design and oversee construction of the skatepark, which will be located on city-owned property.

During public commentary, commissioners were given an update on the nonprofit Project Grow, which has several gardens located in city parks and is celebrating its 40th anniversary this year. Another speaker urged commissioners to take control of the parking lots in city parks, and possibly increase revenues by installing metered parking.

Parks & Rec Budget Recommendation

Park commissioners considered two resolutions related to the city's fiscal year 2013 budget, for the year beginning July 1, 2012 through June 30, 2013. It's the second year of a two-year budget planning cycle. PAC had previously recommended approval of budgets for both years at its April 2011 meeting. The parks budget is part of the city's overall budget, which city administrator Steve Powers proposed at the April 16 meeting of the Ann Arbor city council.

Most of these changes have already been implemented, as part of the current year's budget. Colin Smith, the city's parks and rec manager, reminded commissioners that there will be no increase in budgeted expenses. These changes will be made within the budget plan that was discussed last year for FY 2013, when the FY 2012 budget was formally adopted. [.pdf of budget resolution adopted by council for FY 2012, including parks-related items]

The portion of the city budget relating to parks is separated into two parts: (1) park operations; and (2) parks and recreation.

Sam Offen, who chairs PAC's budget and finance committee, noted that the budget is in better shape than in recent years. He joked that it makes his job much easier.

Parks & Rec Budget Recommendation: Parks Operations Budget

PAC was asked to approve recommendations for the FY 2013 parks operations budget, which includes the following proposed changes: (1) increasing the frequency of the mowing cycle from every 19 days to every 14 days; (2) increasing seasonal staffing between April 15–October 15 to maintain active recreation areas better; (3) establishing three seasonal park steward/supervisor positions to improve park maintenance and enforcement; and (4) increasing seasonal staffing at the ice arenas to improve facility cleanliness. [.pdf of parks operations budget recommendation]

There was considerable discussion about whether to change the wording on the recommendation for the mowing cycle. Tim Doyle initially felt it sounded too much like a dictate rather than an objective, and preferred deferring to staff's judgement on the exact number of days in the cycle. After some wordsmithing on a possible amendment, Christopher Taylor – PAC's ex officio member who also serves on city council – was asked whether his council colleagues would understand the intent. "Contextually, it's plain enough," he said.

Ultimately, PAC reached a consensus not to change wording on the recommendation.

Outcome: Commissioners voted unanimously to recommend approval of the FY 2013 parks operations budget.

Parks & Rec Budget Recommendation: Parks & Rec Budget

In a separate resolution, PAC was asked to recommend approval of the FY 2013 parks and recreation budget. The resolution commended parks staff for its work, and made several general recommendations: (1) reduce energy expenses to reflect the benefit of infrastructure energy improvements at recreational facilities, including Cobblestone Farm and Mack Pool; (2) reduce materials and supplies used to maintain various facilities as a result of recent improvements; (3) reduce water usage expense to reflect actual usage better; (4) eliminate unnecessary software installations where appropriate; (5) increase revenue by initiating additional programming at the Argo Cascades; and (6) increase revenue by increasing fees for admission to swimming pools. [.pdf of parks & rec budget recommendation] [.pdf of fee increases]

Most of these items have been started in the current fiscal year, Offen noted, and will continue into FY 2013.

Outcome: Commissioners unanimously recommended approval of the FY 2013 parks and recreation budget.

Parks Millage Renewal: Public Hearing

No one spoke during a public hearing on the renewal of the city's park maintenance and capital improvements millage, which will likely be on the November ballot.

Park commissioners had been briefed by staff about the millage renewal at PAC's March 20, 2012 meeting.

John Lawter, PAC's vice chair who was presiding over the meeting in the absence of chair Julie Grand, noted that two of the four public informational forums regarding the millage had been held.

[The third forum took place on Monday, April 23. The final one is set for Thursday, April 26 from 6:30-7:30 p.m. at the Ann Arbor District Library's Traverwood branch, 3333 Traverwood Drive.]

Colin Smith, parks and rec manager, noted that Grand had wanted to schedule some of the public forums prior to the public hearing at PAC, and prior to a vote by PAC on whether to recommend millage renewal. That way, PAC could respond if any issues arose. However, Smith added, "there seems to be a great deal of relative silence," and nothing has come up to indicate that the city is on the wrong track in seeking renewal. [At an April 11 forum held at Cobblestone Farm, several city parks staff, PAC commissioners, city councilmember Jane Lumm, and two members of the media – from The Chronicle and WEMU – showed up. But only one member of the public came: Eric Meves, a board member at Project Grow who also spoke during public commentary at the April 17 PAC meeting (see below).]

From left: Greg McDonald, assistant manager of city operations for Community Television Network (CTN), explains a camera problem to Colin Smith, the city's parks and recreation manager. The controller that allows CTN staff technicians to remotely control cameras in city council chambers wasn't working during the April 17 park advisory commission meeting. CTN staff instead adjusted the cameras manually prior to the meeting, to capture wide angle views of the proceedings.

Gwen Nystuen observed that it's hard to get people excited now about a vote that won't happen until November. She said she hadn't heard anything unfavorable about the millage, and that people in Ann Arbor are very supportive of parks. "I'm optimistic," she said.

Sam Offen asked whether there were any significant comments or feedback from the first two forums. Lawter reported that the one person at the forum he attended was supportive. [That person was Meves.] Nystuen praised the staff – she said they had done a good job of answering questions at the first forum about how the budget was prepared.

Informational handouts are being distributed, and Smith pointed out that information about the millage renewal is also available on the city's website.

Windemere Park Tennis Courts

Parks planner Amy Kuras gave a presentation on the tennis courts at Windemere Park, a nearly four-acre parcel on the city's northeast side, north of Glazier Way between Green and Earhart roads. There was no action requested of PAC at this meeting – the staff just wanted to update commissioners on the situation.

The courts were initially built in 1986, then color coated in 2007. Repairs to cracks in the court were attempted in 2009, Kuras said, but failed because of poor soil conditions. The city also attempted to install new net posts in 2009, but that also failed.

In 2010, the city took soil borings in five parts of the park. The borings revealed saturated organic soil and fill, particularly in areas located near the tennis courts in the west part of the park.

Part of the problem is a high water table, Kuras said. In fact, the parks staff have noted higher water tables throughout the city, she added. The only hard data that the city has collected on the water table is at the municipal airport, and there the water table measures between 2-7 feet below the surface now, compared to 15 feet below the surface 50 years ago. Jen Lawson, the city's water quality manager, attributed the change to a variety of factors, Kuras reported, including climate change and more impervious surfaces in the city.

Kuras presented a chart showing cost estimates to replace either one or both courts at the current location. She based her estimates on work done for tennis courts at Veterans Memorial Park and West Park. The total would be $181,377 for two courts at Windemere, or $107,408 for one court. [Link to chart of itemized replacement costs.]

The options to consider, Kuras said, include: (1) replacing both tennis courts at the current location, (2) replacing the courts in another part of Windemere Park, (3) replacing only one court, (4) removing

the courts, or (5) possibly putting the courts in another park.

Matt Warba, the city's acting field operations manager, told commissioners that he's frustrated by the situation. The staff has attempted several repairs, but with water at just two feet below the surface, it's difficult. There's a likelihood that having tennis courts at that location isn't reasonable, he said. But he understands the value to the neighborhood, and the staff is still working on getting some firm numbers and options to consider. There's no easy or quick solution, he said, but they're working on it.

Cracked pavement at the Windemere Park tennis court. (Image provided by city staff in a slide presentation to PAC.)

Windemere Park Tennis Courts: Public Commentary

Jeff Alson told commissioners that he has lived near the park since the late 1970s. He bought his home there in part because of the park. There are a lot of tennis players in the neighborhood, and there are a lot of young children in the area so demand could grow. But because of water issues there's only one court that can be used. Last summer, he hardly played there at all. Alson said he understood that there are problems with water that make maintenance of the courts more expensive. But he emphasized that the courts have held up well for at least the last 10 years, and he would consider it a good investment. It would be disappointing to him if the courts were removed. Alson concluded by thanking commissioners for their service to the city.

Windemere Park Tennis Courts: Commission Discussion

David Barrett asked whether the water table is the same throughout the park. Yes, Kuras said, but the soil composition is different at certain locations in the park – that's a factor, too. She clarified that there are water table issues at other parks, but nothing to the degree they're seeing at Windemere.

Barrett recalled that when the city decided to put in rain gardens at Burns Park, they were slow to let the community know about it. He wondered what kind of outreach was happening for the tennis courts at Windemere. Colin Smith, parks and recreation manager, indicated that outreach would occur when the staff had more information to share. If it makes sense to move the tennis courts, the neighborhood would need to be engaged, he said.

Tim Doyle asked is there's evidence of this same kind of problem at other city tennis courts. He said he's encountered it on a similar project he's working on near Honey Creek, on the west side of town. Warba said that certainly there are areas in the parks that are wetter than they've been in the past. But the Windemere courts are the worst by far.

Sam Offen noted that there are a lot of city tennis courts on the west side of town, but he wondered how many there were on the northeast side. Kuras reported that there are three courts in Leslie Park and two in Sugarbush Park, and it might be possible to accommodate new tennis courts somewhere in Foxfire North Park. All of those parks are in northeast Ann Arbor.

Jeff Alston, a resident who'd spoken during public commentary, pointed out that the courts at Sugarbush are too short for adults to play – they hit the back fence with their rackets, he said.

Gwen Nystuen said she didn't know too much about tennis courts, but that it seemed like the city should assess the distribution and conditions of all of its courts, as well as their overall usage, to get a better idea of where the greatest needs are.

Commissioners and staff also discussed the availability of tennis courts at Ann Arbor public schools, noting that certain times of day and certain days of the week those courts are heavily used by students. Tim Berla noted that Ann Arbor Rec & Ed runs tennis leagues, as does the Ann Arbor Area Community Tennis Association. He pointed out that court conditions aren't just a concern for the city parks – a sinkhole developed at the relatively new tennis courts at Skyline High School, putting one of

the courts out of commission. Berla suggested looking at other materials, such as clay, which he said required more maintenance but wouldn't crack.

Assuming there's need for more tennis courts on the northeast side of town, Berla wondered whether the former Pfizer property – now owned by the University of Michigan – could be a possible location for new courts. He noted that there's a lot of unused land there, as well as available parking.

Drain Project at Veterans Memorial Park

Scott Miller, an engineer with the Washtenaw County water resources commissioner's office, was on hand to give a presentation about a drain project that would affect Veterans Memorial Park. He said the county had been petitioned by the city to do this project. It's referred to as the West Park Fairgrounds project, which is the name of the drain that runs through that section of town – on the west side of town, in the former fairgrounds area. Miller acknowledged that it was a bit confusing, given that a park in a different location is called West Park.

Scott Miller of the Washtenaw County water resources commissioner's office describes an upcoming drain project that will affect Veterans Memorial Park.

The upper end of the drain is located in the Maple Village Shopping Center, where Kmart and Plum Market are located. The drain starts out as a 30-inch pipe and quickly transitions to a 54-inch pipe and then a 66-inch corregated metal pipe as it runs toward town. The pipe runs through Veterans Memorial Park, crosses under Dexter Road and heads east, eventually connecting to a pipe that contains another branch of the Allen Creek.

The city conducted video inspection of the pipe and found several sections that are cracked and corroded, resulting in leaks. Portions of the pipe were clogged with debris. [The city council voted at its Sept. 20, 2010 meeting to petition the county water resources commissioner for this project, estimated to cost roughly $2 million. It will be repaid by the city in annual installments over 15 years.]

Miller said the county staff began work last fall, first clearing the debris and then conducting another video assessment. That revealed two sections of the pipe that have a significant sag, and result in water being held in those sections year-round. One sagging section is in the parking area in the shopping center. Another is in the north side of the park's parking lot that's accessed off of Dexter Road. The preliminary design is to dig up the two sections of sagging pipe and replace them. For the rest of the pipe, the plan calls for putting in a cast lining to reinforce the pipe structurally.

The project would cause minimal disruption, he said, but would include some impact to the parking lot and a small portion of the area west of one of the ballfields. The county is coordinating with the city, which is doing road work and water main replacement along Dexter Road, as well as upcoming work to renovate the ballfields in the park.

The project is in the design phase now, Miller said, with construction expected to begin in the fall.

Drain Project at Veterans Memorial Park: Commission Discussion

Gwen Nystuen asked for more details about how much land would be dug up for the project. Miller reported that in the Maple Village lot, a section about 15 feet wide and 150 feet long would be excavated. In Veterans Memorial Park, the work would be about 15 feet wide and 190 feet long.

Nystuen also commented on the confusing name of the project, and Miller agreed: "It's raised confusion at a lot of levels," he said, but they don't have much latitude to change it.

David Barrett pointed out that there's already disruption to the park – a big pile of dirt has been dumped by the ballfield. He wondered if the county had also coordinated with Ann Arbor Rec & Ed, which runs softball leagues in the park. Miller said the drain work hasn't yet started, so the excavated dirt isn't from their project. Matt Warba, the city's acting field operations manager, clarified that it was likely related to road construction there. Parks and rec manager Colin Smith said the parks staff has been coordinating with Rec & Ed since last year regarding work in the park.

Sam Offen asked about the project's timeframe. It will likely take about two months, Miller replied, but more if there's a lot of rain. In response to another query from Offen, Miller said the county is mindful of the potential flooding impact downstream, but noted that this project isn't intended to increase capacity dramatically. There will be more efficient flow, however.

Ann Arbor park advisory commissioner David Barrett.

Tim Berla clarified that Rec & Ed has cancelled its fall season, which starts in August, because of renovation work on the ballfields at three parks, including Veterans. [PAC had recommended those renovations at their February 2012 meeting.] He asked whether it would be possible to do the park portion of the drain project first, to ensure it would be finished by the spring season. Miller said it probably wouldn't matter – the entire project is expected to be done by the spring of 2013 – but he would look into it.

Berla also asked whether the proposed skatepark – to be located in another part of Veterans Memorial Park – would affect the drain project, in terms of adding runoff. Miller said that although the addition of any impervious surfaces would affect runoff, the pipe is underutilized and has the capacity to handle it.

Smith noted that one of the elements of the skatepark design, as reflected in the request for proposals, will be to include stormwater management that meets or exceeds city standards.

Communications & Commentary

Every meeting includes opportunities for public commentary and communications from commissioners and staff.

Comm/Comm: Public Commentary – Parking in Parks

During public commentary, **George Gaston** told commissioners that he recently visited the University of Michigan's Matthaei Botanical Gardens – it's a lovely place, he said. He had noticed that UM now has metered parking there at $1.20 per hour, between 8 a.m. and 8 p.m. Gaston noted that the city leases its Fuller Park parking lot to UM. It was supposed to be a temporary arrangement, but it's been going on for about 20 years. He wondered if the city has considered taking back control of that lot and and making it a metered lot, too. UM hospital employees use it 24/7, Gaston said, but only pay for part of that time. It could be a great revenue source for the city.

Gaston noted that people park their vehicles all day at Island Park and West Park, as two examples. And with UM planning to build a parking structure on Wall Street that would add another 500 spaces to that area, it might be possible to forego leasing the 18 spaces at Riverside Park to UM and adding metered spaces instead. "You might gain real money out of this," Gaston said. There's precedent in the city for 24-hour metered lots – at the Amtrak station on Depot Street, for example. Right now, it seems the city is undercharging the university for parking. With meters, the lots would be available to anyone if they paid. It might make sense to look into this, he concluded.

Comm/Comm: Project Grow – Public Commentary

Eric Meves, a board member of Project Grow, gave commissioners an overview of the nonprofit. He started by referring to Gaston's comments about parking, noting that Project Grow had to buy parking tags at Matthaei for its gardeners there this year. Meves told commissioners that Project Grow is celebrating its 40th anniversary this year, and he's gardened with the group for 39 of those years.

Several Project Grow gardens are in city parks, so he wanted PAC to become familiar with the organization. It's an educational organization, with assistance for low-income residents. Although the nonprofit has received city funding in the past, it no longer receives public money, he noted.

Project Grow doesn't own any land. About a third of the gardens are located in Washtenaw County parks, and a third on Ann Arbor public school property. The remaining third is evenly divided between

UM land, private property, and city of Ann Arbor parks. About 300-350 families have garden plots each year, Meves said. People do it to grow food, but also for outdoor exercise and to be in a pleasant environment, he said. There's also an element of community – being with your fellow gardeners.

Eric Meves, treasurer of the Project Grow board.

The nonprofit grosses about $40,000 to $50,000 annually, Meves said. About 60% of that comes from plot fees – it costs about $130 for a full plot. About 20% of revenues come from fundraising, primarily through an annual plant sale. The remaining 20% comes from an organic gardening class that Project Grow developed for Washtenaw Community College.

Roughly half of those revenues allow Project Grow to have one half-time employee who works out of his house, Meves said. The group relies on volunteers and a working board. The rest of the funds are used to pay for things like water, utilities, insurance and capital improvements. There are about 40 people on a waiting list for gardens now – demand for gardens is about two to three times what Project Grow can provide, he said.

Meves unfurled a map that he said was made with the help of Merle Johnson and Dan Rainey of the city's information technology department. It showed possible additional locations for gardens within the parks system.

Comm/Comm: Project Grow – Manager's Report

Later in the meeting, Colin Smith reported that parks planner Amy Kuras has been working with the Project Grow managing director [Kirk Jones] to draft an agreement that will outline the formal relationship between the city and the nonprofit. It's been a few years since the city funded Project Grow, he said, but because the group uses city parkland, there's still a relationship. The agreement will stipulate what the procedures are for putting gardens into parks. There have been varied reactions to having gardens in the parks, depending on the neighborhood, he noted. Parks staff will share the agreement with PAC when it's ready, he said.

Tim Berla asked if there's anything PAC or the city can do to help Project Grow identify potential locations for more gardens. Kuras said she works with the organization – sometimes she'll be contacted by someone in a neighborhood who's interested, and she'll in turn contact Project Grow, or sometimes Project Grow comes to her. There are certain requirements, she noted. The land needs to be in a sunny area, and have access to a water source. The city also needs to hold a public meeting if a park is being considered for gardens, and sometimes neighbors don't want it, she said.

From left: Park advisory commissioners Tim Berla and John Lawter. Lawter, who chaired the April 17 meeting in the absence of chair Julie Grand, was reviewing procedural rules with Berla before the meeting. Berla's advice: "No one ever did time" for flubbing Robert's Rules.

Smith noted that the agreement with Project Grow will include details about how PAC can be involved in the process of selecting new locations.

Gwen Nystuen said she appreciated that Eric Meves had spoken to PAC during public commentary. She hadn't realized how many people are involved, and how the city provides relatively little land for

the group. It's useful information, she said, especially given the growing interest in the local food movement.

Tim Doyle clarified with Smith that there is no relationship between Project Grow and the city's greenbelt program.

Comm/Comm: Skatepark RFP

Smith reported that the request for proposals (RFP) for a skatepark at Veterans Memorial Park would be issued the following day. [.pdf of skatepark RFP] The goal is to solicit proposals for a consultant to handle design and oversee construction of the skatepark, which will be located on city-owned property.

Tim Doyle asked how the project would be funded. Smith replied that there are three sources for the roughly $1 million cost of the project: (1) private donations – primarily solicited through the Friends of the Ann Arbor Skatepark; (2) a $300,000 state grant; and (3) up to $400,000 in matching funds from the Washtenaw County parks and recreation commission. The Ann Arbor Area Community Foundation is acting as fiduciary for the project.

The city's contribution will be the land and staff time to manage the process, Smith said, not money. It will be a city-owned asset, he said.

In terms of process, a selection committee – which will include members of the Friends of the Ann Arbor Skatepark, as well as city and county representatives – will be relied on to make a recommendation for the designer. That recommendation will be reviewed by PAC. PAC commissioner David Barrett will serve on the committee. Park planner Amy Kuras is the city's point person on the project.

Construction is expected to start in the spring of 2013.

Gwen Nystuen asked about the relocation of pathways that will be required because of the skatepark location. Kuras noted that some pathways in Veterans Memorial Park are being redone as part of the Dexter Avenue improvement project that's currently underway. Paths that connect to the skatepark will be designed as part of the overall skatepark design, she said.

Comm/Comm: Manager's Report – Market Manager

Smith reported that the field had been narrowed to two candidates to replace Molly Notarianni, who left the job of public market manager earlier this year. He said he hoped to have finalized a hire by PAC's May 15 meeting.

Comm/Comm: Manager's Report – Argo Cascades

The same day as the PAC meeting, the consultant who designed the new canoe/kayak bypass by Argo Dam – Gary Lacy of Boulder, Colo. – was testing the series of drop pools along with city staff. Smith said he had hoped that Lacy would have the time to give an update to PAC about the new Argo Cascades, but the morning had been chilly and Lacy had gotten a late start on the testing, so he wasn't able to attend the meeting.

A grand opening of the Argo Cascades is planned for June, but it will be open to the public before that. May 5 is the date for the first trips from the Argo Pond livery to Gallup Park, Smith said.

Present: David Barrett, Tim Berla, Doug Chapman, Tim Doyle, John Lawter, Karen Levin, Gwen Nystuen, Sam Offen, councilmember Christopher Taylor (ex-officio). Also Colin Smith, city parks and recreation manager.

Absent: Julie Grand, councilmember Mike Anglin (ex-officio).

Next meeting: PAC's meeting on Tuesday, May 15, 2012 begins at 4 p.m. in the city hall second-floor council chambers, 301 E. Huron St., Ann Arbor. [confirm date]

   We encourage action, soon. This problem has existed for a long time without solution. Just listen to the nearby neighborhoods say the demand is there and fix a community resource. Seems like a sunk cost without adequate maintenance.

   Consider a local bond issue or ~ and do something.

Mr. Matthew J. Kulhanek, Airport Manager
Ann Arbor Municipal Airport
801 Airport Road
Ann Arbor, Michigan 48104

Dear Mr. Kulhanek:

Subject: Ann Arbor Municipal Airport

Enclosed is a conditionally approved copy of the Ann Arbor Municipal Airport, Airport Layout Plan (ALP), dated April 2008. This letter cancels or supersedes all prior ALP approvals. The ALP approval is based on recognition of and adherence to the following:

1. The approval is not to be considered a commitment of Federal funding for the proposed development. The FAA has concurred with the proposed development for planning purposes only based on current safety, utility, and efficiency standards. Actual development should comply with approved standards applicable at the time of construction. The airport will need to provide the FAA justification of need before seeking FAA financial participation in the following projects;
   - Shift and extension of runway 6-24 with proposed approach improvements;
   - Associated parallel taxiway construction for the above referenced runway;
   - Identification of a future terminal development area;
   - Achieving the lowest possible minimums for the airport including the installation of additional NAVAIDs; and
   - Purchasing additional land and clearing all objects necessary to meet approach and Part 77 requirements necessary for development and protection of FAA design criteria.
2. No design standard modifications have been granted.
3. We note the following:
   a. If any runways are to be shifted or extended, the shift/extension must be designed such that Standard Runway Safety Areas and Object Free Areas are maintained.
   b. If any design critical aircraft or aircraft group changes for the runway identified, this ALP must be reevaluated by the FAA.
4. Our approval does not infer or imply that the land in the airport vicinity is considered compatible with airport operations. Federal requirements stipulate:
   a. All development programs should be reasonably consistent with the plans of local and state planning agencies for the development in the airport vicinity.
   b. That fair consideration has been given to the interest of communities in or near the airport.
   c. That development programs provide for the protection and enhancement of the environment.
5. The FAA offers no objections to the proposed ultimate airspace utilization as depicted on the ALP based on considerations of safe and efficient use of airspace. The ALP has the status of "Plan on File" for the purpose of 14 CFR 77, Obstruction Evaluations, and 14 CFR 152, Airport Aid Program. A review of the airside landing area development was conducted according to the following 14 CFR's: -77, -152, and -157, Notice of Construction, Alteration, Activation, and Deactivation of Airports (reference Aeronautical Study Number 2008-AGL-533-NRA). It should be noted that FAA cannot prevent erection of any structure near an airport. Airport environs can only be protected through state and local zoning ordinances, building regulations, and like requirements. Please refer to the FAA Airspace Approval letter dated June 8, 2008 for additional detailed information.
6. All development depicted on this ALP must comply with the National Environmental Policy Act (NEPA) of 1969. FAA environmental approval is required for all airport development actions depicted on this ALP. This would apply to development projects, even if there were no FAA funding involved in the project. Additional requirements concerning FAA NEPA approval can be found in FAA Order 5050.4B. *"National Environmental Policy Act (NERPA) Implementing Instruction for Airport Actions."*
7. To avoid conflicts with future development, we recommend you utilize the ALP when preparing leases. We further recommend you provide copies to the local and state planning zoning boards and county and city officials and encourage them to adopt compatible land use criteria in and around the airport. Copies should also be distributed to the Fixed Base Operators (FBO's) and airport users.
8. The Airport and Airway Improvement Act (49 USC 47107 (a) (16) (D)) requires the sponsor to eliminate any adverse effects on Federal facilities, or bear all costs to relocate those facilities, that are a result of an airport change. However, if AIP eligible construction/development items adversely affect FAA facilities, the cost of relocating the facilities may be eligible under AIP. If the proposed development requires any displaced or relocated FAA facility, the construction will have to be coordinated with the FAA in order to establish reimbursable funding for the engineering and relocation.
9. This approval does not include a detailed evaluation of actual construction. Prior to constructing any development on the airport, notice (FAA Form 7460-1) consistent with 14 CFR 77 must be filed with this office. This approval does not include approval for temporary construction equipment which may be used during actual construction, e.g., cranes, equipment staging areas, site access routes, etc. A separate construction safety/phasing plan for any project should be reviewed by the FAA no less than 60 days prior to beginning any project. The airport must take all measures necessary during construction to ensure there are no runway incursions.
10. If development is planned without aviation trust fund investments that will change the status or geometrics of runways, taxiways, aprons, or other operating airport surfaces, notice (FAA Form 7480-1) must be filed with this office consistent with 14 CFR 157.
11. The planned runway developments will require new FAA flight procedures. If the FAA concurs with these developments there will need to be close coordination with different FAA offices. Development on new approaches will not begin until environmental approvals have been given and the sponsor requests the FAA Flight Procedures Office to initiate design of new approaches. Publication of revised Instrument Approach Procedures (IAPs) could take from 18 months to two years, after runway data is submitted. Review of this ALP does not constitute an automatic request for amended procedures.

We trust this letter provides a clear explanation of the conditions and terms of our approval. If you desire further clarification, please contact John D. Pierce at 517-335-9857.

Sincerely,

David L. Baker, PE, Manager

May 11, 2006

Mr. James R. Hawley, Manager
Ann Arbor Municipal Airport
801 Airport Road
Ann Arbor, Michigan 48104

Dear Mr. Hawley:

Subject: Ann Arbor Municipal Airport, Ann Arbor, Michigan
Airport Layout Plan (ALP) Airspace Approval
Airspace Case No. 06-AGL-0008-NRA

Enclosed is one approved copy of the Ann Arbor Municipal Airport Layout Plan (ALP), dated January 10, 2006. This ALP is being approved on behalf of the FAA under the authority of Section 534 of the Airport and Airways Improvement Act (AAIA) of 1982 as amended, pursuant to the State Block Grant program. This letter cancels or supersedes all prior ALP approvals. The ALP approval is based on recognition of and adherence to the following:

1. The approval is not to be considered a commitment of Federal funding for the proposed development. The FAA has concurred with the proposed development for planning purposes only based on current safety, utility, and efficiency standards. Actual development should comply with approved standards applicable at the time of construction. No design standard modifications have been granted.

   If any of the design critical aircraft or aircraft groups change, this ALP must be reevaluated by the FAA.

2. Our approval does not infer or imply that the land in the airport vicinity is considered compatible with airport operations. Federal requirements stipulate:

   a. All development programs should be reasonably consistent with the plans of local and state planning agencies for the development in the airport vicinity.

   b. That fair consideration has been given to the interest of communities in or near the airport.

   c. That development programs provide for the protection and enhancement of the environment.

3. The FAA offers no objections to the proposed ultimate airspace utilization as depicted on the ALP based on considerations of safe and efficient use of airspace. The ALP has the status of "Plan on File" for the purpose of 14 CFR 77, Obstruction Evaluations, and 14

CFR 152, Airport Aid Program. A review of the airside landing area development was conducted according to the following 14 CFR's: -77, -152, and -157, Notice of Construction, Alteration, Activation, and Deactivation of Airports (reference Aeronautical Study Number 05-AGL-942-NRA). It should be noted that FAA cannot prevent erection of any structure near an airport. Airport environs can only be protected through state and local zoning ordinances, building regulations, and like requirements.

4. Approval is given subject to the condition that any proposed airport development requiring environmental processing shall not be undertaken without prior written environmental approval by the FAA. Any airport development action that falls within the scope of Paragraph 24 of FAA Order 5050.4A, or which involves any of the following:

   a. Runway End 24 currently has a NPI approach 20:1 with a displaced threshold.

   b. Purchase additional land in fee and easements for the approach to Runway End 24 to provide for a 15' clearance over State Road for a future 34:1 NPI approach. State Road is proposed to be relocated or lowered to provide this 15' clearance.

   c. Proposed new Air Traffic Control Tower (ATCT).

   d. Proposed new access road to the administration building area.

   e. Proposed additional hangars.

   f. Proposed new drainage system.

   g. Clear, lower or remove obstructions (refer to the Obstruction Table on Sheet 6).

   h. Land acquisition associated with any of the above items plus land acquisition which results in relocation of residential units where there is evidence of insufficient comparable replacement dwellings, major disruption of business activities, or acquisition which involves land covered under Section 4(f) of the DOT Act (rectified 49 USC Subtitle I, Section 303, January 12, 1983).

   i. Any airport development action that falls within the scope of Paragraph 24 of FAA Order 5050.4A, or which involves any of the following:

      i. Use of Section 4(f) lands.
      ii. Effect on any properties included in or eligible for inclusion in the National Register of Historic Places or other property of state or local historical, architectural, archeological, or cultural significance.
      iii. Land acquisition for the conversion of farmland, which scores more than 160 on Form AD-1006 and is protected under the Farmland Protection Policy Act (FPPA), to nonagricultural use through federal financial assistance or through conveyance of government land.
      iv. Wetlands, coastal zones, or flood plains.
      v. Endangered or threatened species.

Any items not covered above in item 4 shall not take place until the environmental processing has been approved by the FAA. All development items must comply with the National Environmental Policy Act of 1969 (P.L. 91-190).

To avoid conflicts with future development, we recommend you utilize the ALP when preparing leases. We further recommend you provide copies to the local and state planning zoning boards and county and city officials and encourage them to adopt compatible land use criteria in and around the airport. Copies should also be distributed to the Fixed Base Operators (FBO's) and airport users.

The Airport and Airway Improvement Act (49 USC 47107(a)(16)(D)) requires the sponsor to eliminate any adverse effects on Federal facilities, or bear all costs to relocate those facilities that are a result of an airport change. However, if AIP eligible construction/development items adversely affect FAA facilities, the cost of relocating the facilities may be eligible under AIP.

This approval does not include a detailed evaluation of actual construction. Prior to constructing any development on the airport, notice (FAA Form 7460-1) consistent with 14 CFR 77 must be filed with this office. This approval does not include approval for temporary construction equipment which may be used during actual construction, e.g., cranes, equipment staging areas, site access routes, etc. A separate construction safety/phasing plan for any project should be reviewed by the FAA no less than 60 days prior to beginning any project.

If development is planned without aviation trust fund investments that will change the status or geometrics of runways, taxiways, aprons, or other operating airport surfaces, notice (FAA Form 7480-1) must be filed with this office consistent with 14 CFR 157.

We trust we have provided a clear explanation of the conditions and terms of our approval. If you need further clarification, please contact John D. Pierce at (517) 335-9857.

Sincerely,

David L. Baker, P.E., Manager

Re: Response to Your April 15, 2019, Letter Requesting Pittsfield Township's Input regarding Ann Arbor Municipal Airport's Proposed 800' Extension of the Runway.

Dear Mr. Ballard,

As you are no doubt aware, Pittsfield Township has been opposed to lengthening the runway at Ann Arbor Municipal Airport (ARB or the "Airport") for social, economic and environmental reasons since the Airport first announced its intention to extend the runway in 2007. Extending the runway defies Pittsfield Township's Resolution opposing such an expansion. It will cause issues with the Township's noise ordinance. And the Township will lose millions of dollars in tax revenues. However, the Airport and MDOT believe that they can ignore Pittsfield Township's wishes and take on a project within its governmental jurisdiction despite the Township's adamant opposition. What makes this situation worse is that the runway extension is not needed. Pittsfield Township has been ignored and marginalized by the Airport and MDOT for 12 years. After 12 years of discussions, which have negatively affected the Township and its residents, this project needs to be set aside for good.

Since a new environmental assessment will be drafted about the extension of the runway, you have asked that the Township address specific issues. What follows is Pittsfield Township's responses to each category you mentioned in your April 15, 2019, letter.

I. Specific Areas of Concern/Regulatory Jurisdiction.

A. There Is No "Purpose" or "Need" for Lengthening the Runway at ARB.

In your April 15, 2019, letter you state that MDOT will be conducting an environmental assessment of the proposed project. Because this Project will be financed with federal funds through the FAA's Block Grant program, MDOT must comply with the federal National Environmental Policy Act (NEPA). This includes a full evaluation of the "Purpose and Need" for extending the runway. Pittsfield Township's primary concern is there is no purpose or need for extending the runway at ARB. An environmental assessment (EA) must include a discussion of the purpose and need for the proposed action which must "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." 40 C.F.R. § 1502.13. In addressing the Purpose and Need section of an EA, FAA Order 1050.1F provides that the Purpose and Need section "presents the problem being addressed and describes what the FAA is trying to achieve with the proposed action. The purpose and need for the proposed action must be clearly explained and stated in terms that are understandable to individuals who are not familiar with aviation or commercial aerospace activities. To provide context while keeping this section of the EA brief, the FAA may incorporate by reference any supporting data, inventories, assessments, analyses, or studies." FAA Order 1050.1F, ¶ 6-2.1c. As it exists, there is no problem at ARB for which an extended runway is the best answer.

1. Use of the lengthened runway would rarely be required but would pose substantial risks to the surrounding community every day.

The Airport has long claimed that an extended runway is needed because the B-II aircraft operating out of ARB "suffer" weight penalties due to the "short" runway. If this is still the case, then the environmental assessment must include any data on B-II operational usage in terms of the number of days or operations when aircraft suffered actual weight penalties, number of aircraft involved, or the actual penalties suffered on the runway. It is only then that a true analysis as to whether the extension is needed can be drafted.

However, it is possible to provide a rough statistical analysis based on usage data of how frequently the expanded runway might be necessary. FAA Advisory Circular 150/5325-4B *Runway Length Requirements for Airport Design* aids an airport in determining the recommended runway length. AC 150/5325-4B, contains a runway length curve utilized with temperatures at 83 degrees Fahrenheit or above, and an ARB elevation of 839 feet, criteria to which MDOT has stipulated, to meet the mean daily temperature during the hottest month at ARB. ARB had 63,107 total operations in 2018, of which, the FAA claims 697 were category B-II operations. An analysis of data from the National Oceanic and Atmospheric Administration Weather Station at ARB shows that in 2015 there were 42 days in which the temperature was 83 degrees Fahrenheit or above. ARB has a based population of 164 aircraft, of which 14 are category B-II aircraft. These data are based on the most current publicly available information at the time of drafting this letter.

With these data, a calculation of potential need of an expanded runway based on maximum potential need can be made. If, on every day on which the temperature reached or exceeded 83 degrees, every aircraft in the B-II fleet operated at its maximum take-off weight – a highly unlikely possibility – and required the expanded runway to take-off, based on the ARB fleet population the need for the expanded runway would be 0.00848, or 8.5 in 1,000 (42/365 x 14/164). This is based on the number of days with temperatures exceeding 83 degrees and the proportion of the total ARB fleet that is Category B-II. However, if this calculation were based on the more realistic actual usage in the most recent operational year (2018), on every day the temperature reached 83 degrees or above, the actual need for an expanded runway would be 0.00127 – or about 1.25 in 1,000 (42/365 x 697/63107) – the number of B-II operations relative to the total operations in the most recent year of 2018.

Thus, operational need for an expanded runway would be rare. Based on statistical analysis the expanded runway would be necessary for approximately 50 operations per year, at most. Yet, it would place citizens in the surrounding community at risk hundreds of times more frequently because aircraft would be taking off and landing 950 feet closer to residential areas, and larger and heavier aircraft will be attracted to ARB by the expanded runway. The area to the west and south of the Airport – just off the most frequently used end of the runway – is heavily residential. The Airport is not in a rural setting and more homes are being constructed close to the Airport. These risks are exacerbated because of the potential dangers posed by aircraft that would be landing just 93 feet over homes in an area heavily populated with Canada geese just west of the airport, and by the reduced margins of safety if an aircraft suffers an engine failure on or just after takeoff. Such aircraft can lose their climbing power with an engine loss and could crash into the heavily-populated neighborhood. The risk of – and liability from – such a potential accident has not been studied and should be as part of any assessment about the purpose and need of extending the runway at the Airport.

2. The "problem" that the Airport claims needs fixing is overstated.

In the April 15, 2019, letter to Pittsfield Township, MDOT stated that the document would be developed under FAA Order 1050.1F, "Environmental Impact: Policies and Procedures." Section 6-2.1(c) of Order 1050.1F defines "need" as the problem and "purpose" as the proposed solution to the problem. The Purpose (*i.e.,* the Project) is supposed to resolve the Need (*i.e.,* the problem). Here it is the opposite, one large tenant's desire (AvFuel Corp.) to extend the runway is driving the proposed action. This is a case of a Purpose looking for a Need. It is a project looking for a problem to justify its existence.

The claimed Need mentioned in the April 15, 2019, letter that an extended runway is needed "to meet the current and future fleet mix needs of the Airport" lacks substantive evidence. The Airport has previously defined the Need as "[n]eed of the proposed actions is to allow the critical aircraft to safely operate at their optimum capabilities without weight restrictions (i.e. reductions in passengers, cargo, and fuel associated with cargo range) due to suitable runway length." But that statement (and the statement in the April 15, 2019, letter) presumes that such critical aircraft cannot already operate at such capabilities regularly. There has been no evidence this is the case.

On the few occasions that a longer runway is needed, Willow Run Airport (YIP) is a short 12 miles from ARB (approximately 15 minutes by car). YIP has three runways (7500, 7300 and 6000) and robust general aviation and business aviation facilities. Thus, the Airport's argument is that the runway needs to be lengthened so a handful of aircraft pilots and passengers need not drive an extra 12 miles to get to/from the airport on the few days that a weight restriction would be required.

This issue of justification of the need to lengthen the runway has been problematic since the idea was first raised in 2007. Even the FAA has questioned the need for an extended runway. In May 2010 comments on the 2010 Draft Environmental Assessment (DEA), the FAA asked, "[h]as it been documented that the current B-II 'small' users operate with load restrictions? If so, how often does this occur and what are the quantifiable impacts to their operations?" The Airport failed to answer the FAA's question. In addition, in a separate question, the FAA asked, "the conclusion for the implementation for the preferred alternative states that a positive result of improvements is the ability of business owners to achieve improved fleet efficiency for critical aircraft by maximizing their passenger and/or cargo loads. How has this statement been substantiated? What records exist that current users at ARB are not operating at maximum passenger and/or cargo loads? What has been the economic impact of the reduction of loads if they are occurring?" To paraphrase the FAA's questions, if there is no established, substantiated loss of passenger or cargo load opportunities, or established current negative economic impact, there is no Need. These questions must be answered before any project to lengthen the runway is even considered by MDOT.

It is also worth noting that MDOT's federal block grant status could be at risk if it does not enforce the requirements under FAA Order 1050.1F in terms of requiring applicants to provide supporting data, inventories, assessments, analyses, or studies to support its proposed expansions, even though MDOT has not traditionally done so.

3. Not all reasonable alternatives have been considered.

The National Environmental Policy Act ("NEPA") (42 U.S.C. §§ 4321 *et seq.*) requires that federal agencies examine all reasonable alternatives in preparing environmental documents. 42 U.S.C. § 4332(c)(iii). An agency preparing an EA should develop a range of alternatives that could reasonably achieve the need that the proposed action should address.

In the past, MDOT has ignored the possibility of using Willow Run Airport (YIP) as an alternative to the proposed project because it was determined that using YIP is not "desirable based on proximity to corporate offices or business needs." This is not a valid reason to not consider an alternative in an Environmental Assessment and in violation of NEPA, NEPA regulations, and FAA Order 1050.1F.

Using YIP instead of ARB meets the purpose and need of the project making it a reasonable alternative that must be considered in the Environmental Assessment. YIP has the runway length and facilities to accommodate the aircraft that may be weight-restricted from using ARB. The only reason given to dismiss it from further consideration is that it is located 12 miles from ARB and that it is a slight "inconvenience" to the corporations who want to use ARB instead of YIP. Even if lengthening the runway would benefit more than one or two aircraft, this is not an appropriate reason to dismiss an alternative from further consideration in an Environmental Assessment. If an alternative is "reasonable" (*i.e.,* it meets the purpose and need) then it must be considered in the Environmental Assessment alongside the preferred alternative and the no action alternative. *Friends of Southeast's Future v. Morrison*, 153 F.3d 1059, 1065 (9th Cir. 1998). Since using YIP instead of ARB would achieve the purpose and need of allowing "critical aircraft" to take-off and land without weight restrictions, it is a reasonable alternative and must be fully analyzed as part of the Environmental Assessment process.

B. Expanding the Runway Will Result in an Increase in Violations of Pittsfield Township's Ordinances and Planning Procedures

1. Noise Ordinance

Pittsfield Township, within which ARB is wholly located, has a long-standing noise ordinance making it unlawful for "any person to create, assist in creating, permit, continue, or permit the continuance of any unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township." Pittsfield Township has a duty to protect its citizens' health, safety and property from "unreasonably loud, disturbing, unusual or unnecessary noise."[1]

How the lengthening of the runway will affect the enforcement of this ordinance has not been examined, as required by NEPA, NEPA Regulations and FAA Order 1050.1F. If the ARB runway was expanded to the west, as proposed, and the noise impacts on Pittsfield residents were to change, this ordinance would face demands from citizens for more strenuous enforcement.

Therefore, all aircraft flying in and out of ARB are subject to Pittsfield's noise ordinance and fines can be levied on the aircraft owners for operating their aircraft if they create an "unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace, or safety of others within the limits of the township."

[1] See attached Exhibit A.

2. Violation of Agreements between the City of Ann Arbor and Pittsfield Township.

The Airport and Pittsfield Township have a long and contentious history. In 1979 Pittsfield Township and the City of Ann Arbor, the owner of ARB, reached an agreement intended to resolve issues at the Airport.[2] In 2009, a new agreement was reached that incorporated the 1979 Agreement and sought to instill a sense of cooperation between the City of Ann Arbor and Pittsfield Township on issues regarding the Airport.[3] The 2009 Agreement is up for renewal this year.

It is Pittsfield Township's position that extending the runway at ARB is a violation of the 2009 Agreement, if not to the letter of the agreement, at least to the spirit of the agreement. The 2009 Agreement was meant to foster cooperation between the City of Ann Arbor and Pittsfield Township on issues related to the Airport. However, the Airport's insistence on extending the runway over the strong opposition of Pittsfield Township is not being "cooperative." Since the 2009 Agreement is set for renewal on October 1, 2019, Pittsfield Township is considering not renewing the agreement. Pittsfield Township would then require that ARB comply with Pittsfield Township's ordinances, planning procedures and construction codes. Pittsfield Township will also consider passing an ordinance requiring all airports within its jurisdiction to receive approval from the Township Board of Trustees before extending any runway at an airport in Pittsfield Township.

C. "Safety" Issues Do not Justify Runway Expansion and Increase dangers to surrounding Communities.

One of the primary issues facing this project is that when the FAA and MDOT emphasize "safety," they are talking about safety regarding the airport, its airplanes, and their fliers. None of the environmental documents drafted have mentioned a concern for the safety or well-being of citizens in the communities surrounding the airport. This is especially troublesome given that two small jets crashed nearby – one on a runway comparable to that proposed for an expanded ARB, a crash which could have been catastrophic had it occurred at ARB.

Historically, MDOT has claimed that a goal of the Project is to prevent overruns. MDOT has concluded "[t]here is no evidence in the incident reports that any of the aircraft which overran the end of the existing 3,505-foot runway exceeded the limits of the 300-foot-long turf Runway Safety Area (RSA). Therefore, in each of these cases, the proposed 4,300-foot runway would have provided sufficient length for the small category A-1 aircraft to safely come to a stop while still on the runway pavement, without running off the runway end." Revised Draft Environmental Assessment (RDEA), p.25. However, our review of the 11 runway overrun incidents shows they were all the result of pilot error or mechanical problems – one as careless as the lack of marking construction areas on the

[2] See attached Exhibit B.
[3] See attached Exhibit C.

runway itself by the airport operator, so the pilot was unaware of a construction berm. The FAA agreed these incidents did not support runway expansion, concluding in its comments to the 2010 DEA, "…[t]he local objective of reducing runway overrun incidents appears to conclude that if the added runway length were present, all the incidents would have been avoided. Based on the information presented, the FAA does not necessarily come to the same conclusion. There are many factors that go into any overrun incident and if additional runway length were present this may have only prolonged the overrun incident. The A-1 category of aircraft involved with the overrun incidents do not appear to have needed any length beyond the existing runway length to operate at full capacity and in a safe manner." RDEA, Appendix J, FAA letter dated 5-13-10, pp. 5-6, ¶¶ 7 (p.5) and (p.6).

But there is evidence that expanding the runway could lead to *additional* runway excursions. This results from the potential dangers created by attracting more business jets because of the extended runway length. On February 11, 2016, the National Business Aviation Association reported that runway excursions by business jets on landings cause about one-third of all runway excursions, making them the most common business aviation accident, about twice weekly somewhere in the world for about $900 million annually. These incidents are frequently caused by not aborting landings when pilots should, landing at unfamiliar airports, and landing too fast and too far down the runway. The added risk for ARB is these larger jet aircraft, with larger fuel payloads, could pose added challenges to firefighters if an emergency occurs. Those firefighters are not based on the ARB airport, which does not actually provide on-site fire and rescue services – and are provided by Pittsfield Township.

One such excursion occurred nearby – just 20 miles northwest of Ann Arbor on January 16, 2017, at the Livingston County Spencer J. Hardy Airport (OZW) in Howell, when just such an unfamiliar pilot attempted to land his Cessna Citation 525 CJ4, but crashed on landing, destroying the aircraft and injuring the pilot. The pilot, who was the only one aboard the 10-passenger, twin-engine jet, apparently lost control on landing, skidding off the end of the runway, through a fence, across a road, and striking a clump of trees, tearing the wings from the fuselage, and causing a fire. Witnesses helped the pilot from the wreckage before emergency crews could arrive (L.T. Hansen, "Report: Plane with single occupant crash-lands at Livingston County Airport," *MLive.com*). The distance from the end of the runway to the trees is about 1,800 feet.

This is important because while the Livingston County airport runway is 5,000-feet long – 700 feet longer than the proposed ARB extended runway – the aircraft would have been more than capable of landing on an expanded ARB runway of 4,300-feet. And, the Runway Safety Zones (RSZs) and Runway Protection Zones (RPZs) frequently mentioned by MDOT as protecting neighborhoods surrounding airports from the effects from potential aircraft accidents, afforded no such benefits. If a similar incident were to have occurred at an expanded ARB, with a high-speed jet crashing, skidding not just 1,800 feet, but 2,500 feet – because the Livingston County airport runway was longer – beyond the end of an expanded 4,300-foot ARB runway, and burning, it could have ended up in homes across Lohr Road from the end of the runway, which could have been deadly!

The NTSB has reported on the significant danger of crashes in private and charter airplanes vs. commercial aircraft, the aircraft likely to be attracted to an expanded ARB. Between 2000 and 2015, the NTSB found there were five times fatal accidents in the U.S. involving private and chartered corporate planes than airlines. Investigators cited pilot error in 88 percent of the crashes, noting crews skipping safety checks, working long days, missing rest periods, overlooking ice on wings, or trying to land when they could not see the runway as among the causes of crashes ("Private Jets Have More Fatal Accidents than Commercial Planes," A. Levin, May 15, 2015, *Bloomberg News*).

The best way for an ARB surrounded by population centers to avoid such potential tragic problems is to not expand the existing airport and invite such larger and heavier jet aircraft to impose such dangers and risks given the small benefit any expansion would provide. The airport is safe and presents no such dangers.

II. Specific benefits and detriments of the project for your organization or to the public.

The project has no benefits to Pittsfield Township, only detriments and costs. The project will substantially harm Pittsfield Township and its neighbors. Specifically, Pittsfield Township and the surrounding communities will lose needed tax revenue because of diminished property valuations. In addition, the surrounding communities have specifically told the Airport they are opposed to lengthening the runway.

A. Runway expansion could cause Pittsfield Township to lose millions of dollars from reduced taxes.

There is extensive research to suggest an extension of the runway could cause severe economic losses to several communities surrounding the airport, including Pittsfield Township, in reduced real estate values and, reduced property and school taxes based on assessed property values. Extensive research based on other communities in which airport runways have been extended – Atlanta, Reno-Tahoe, Chicago O'Hare, the Greensboro-High Point-Winston Salem metroplex, 23 cities in Canada, among others – show property values decline as runways are expanded. The most respected such study. *The Announcement Effect of an Airport Expansion on Housing Prices*, G.D. Jud & D.T. Winker, (2006), JOURNAL OF REAL ESTATE FINANCE AND ECONOMICS, 33, 2, 91-103, suggests house prices decline by about 9.2 percent within a 2.5-mile band of the airport, and, beyond that, in the next 1.5-mile band, prices decline another percent once an announcement – without extraneous influences – was made.

The lengthy hold up of the proposed ARB expansion has represented an extraneous influence since the initial announcement in 2007, but that if approved, these effects would occur at ARB. To further support this claim, a literature search could find no published, peer-reviewed research study where residential real estate values continued to rise in areas immediately surrounding an airport after runways were expanded. A decrease in property values in the areas surrounding ARB would have important consequences for the governmental bodies that benefit from property tax collections. In the corridors referenced in the Jud & Winker study noted above, there are:

- 6,239 Pittsfield Township parcels of land within the 2.5-mile area surrounding the airport; and
- 4,168 parcels within the 2.5-mile to 4-mile area.

These parcels will be subjected to a decline in real estate values of 9.2 percent and 5.7 per cent, respectively due to the expanded runway. Using those facts, the following is the estimated value of what the potential **annual** losses in property tax revenue would be for various governmental bodies based on their tax collections in the year following the extension of the runway:

- $1.5 million less for the Ann Arbor School District;
- $1.4 million less for the Saline School District;
- $850,000 less for Pittsfield Charter Township; and,
- $810,000 less for Washtenaw County.

This estimate is only for property in Pittsfield Township. These numbers understate the decline in tax revenues, because they do not consider the potential effects of property in Lodi Township, the City of Saline, (both of which could affect the Saline School District's revenues), or property in the City of Ann Arbor. Thus, governmental bodies could stand to lose millions of dollars in operating funds annually from a runway expansion project that has yet to demonstrate any real economic benefit.

B. The Airport must consider the interests of local communities.

Both Pittsfield Township, where ARB is located, and neighboring Lodi Township have passed Resolutions, (March 24, 2009,[4] and May 12, 2009,[5] respectively) opposing an expansion of the runway at ARB. The Resolutions oppose the expansion because of the risks from Canada geese in areas surrounding the airport, low-flying aircraft on the approaching newly expanding runway, and that 99 percent of the based aircraft can operate at their full weight capacity on the existing runway. More important, though, the Resolutions seek to protect the health and property rights of their citizens.

The Airport has ignored these Resolutions in the past and will do so again unless FAA or MDOT take them seriously when conducting an environmental assessment. Ignoring the resolutions violates NEPA, NEPA Regulations and FAA Order 1050.1F, it is also a violation of Ann Arbor's federal grant assurances, exposing the Ann Arbor to

[4] See attached Exhibit D.
[5] See attached Exhibit E.

litigation liability and potential loss of all federal funding for ARB. If the runway is necessary, the ARB should meet with the Township and explain why the Resolutions should be rescinded. Going forward with the project without the sign-off of the Township is not being a good neighbor or keeping with the spirit of cooperation regarding Airport issues.

Given Pittsfield and Lodi's resolutions of opposition, the expansion of the runway contradicts the will of those governing bodies. The expansion would benefit a minute number of airport users – while placing at risk thousands of members of the Pittsfield and Lodi communities with added larger and heavier aircraft, flying much closer to their homes, at lower altitudes, in an area heavily populated by Canada geese, and in an increasingly dense residential area.

The consideration of the wishes of these local communities must be weighed and evaluated and given "fair consideration" as required by the FAA's grant agreement with Ann Arbor. In the ten years since the proposed expansion has been pending, for example, not even one study on the potential safety effects of the expansion on the residents of Pittsfield has been conducted. ARB and MDOT have consistently ignored the interests of communities surrounding ARB.

C. Any Environmental Assessment Must Properly Consider the Intensity of the Impacts on the Surrounding Community.

NEPA Regulation 40 C.F.R. § 1508.27 requires that the Project be placed in context with the surrounding society so the Project's impact on the affected region, the affected interests, and the locality can be properly evaluated. Any environmental document undertaken by MDOT must adequately address this aspect before the Project can be approved. This aspect of the environmental assessment process is often called "Intensity," and it requires consideration of:

> (1) Impacts that may be both beneficial and adverse. A significant effect may exist even if the Federal agency believes that the effect will be beneficial.
> (2) The degree to which the proposed action affects public health or safety.
> (4) How much the effects on the quality of the human environment are likely to be highly controversial.
> (5) How much the possible effects on the human environment are highly uncertain or involve unique or unknown risks.
> ….
> (10) Whether the action threatens a violation of Federal, State, or **local law** or requirements imposed for protecting the environment."

40 C.F.R. § 1508.27 (emphasis added). *See also* FAA Order 1050.1F, § 4-3.2, p.4-3.

This proposed project has a statistically small benefit (.00175), and yet would attract larger and heavier jet aircraft in closer proximity to homes in areas heavily populated with Canada geese, potentially jeopardizing residents if an accident occurs – accidents that the FAA contends are the third most frequent that occur in terms of incidents with hazardous wildlife in aviation. The risk to public safety may far outweigh any established benefit, which has not been substantiated. Added risks in terms of additional noise and night flights have not been established, but with arrival traffic traveling just 93 feet over rooftops on an expanded runway, it could have a controversial and negative impact on the human environment of citizens in Pittsfield Township, in violation of that township's noise ordinance and resolution, and in violation of federal law.

III. Any Available Technical Information/Data for the Project Site

A. ISO 1996-1:2016 Must Be Used in Assessing Noise Impact to the Community Surrounding ARB.

ISO 1996-1:2016, entitled "Acoustics -- Description, measurement and assessment of environmental noise -- Part 1: Basic quantities and assessment procedures," which was published in March 2016, defines the basic qualities to be used for the description of noise in community environments and describes basic assessment procedures. ISO 1996-1:2016 predicts the potential annoyance response of a community to long-term exposure to noise based on characteristics of the community rather than based on the noise created. As a product of the International Organization for Standardization, ISO 1996-1:2016 represents the best science for assessing the impact of noise on affected communities. The FAA requires that the best scientific methods be used in technical matters to comply with the Data Quality Act (also called the Information Quality Act). Therefore ISO 1996-1:2016 must be used to avoid a violation of the Data Quality Act.

B. The Project Does Not Account for the Noise Impact of the Project on the Surrounding Community.

1. MDOT and ARB must protect the surrounding community from aviation noise.

It is "the policy of the United States - - that aviation facilities be constructed and operated to minimize current and projected noise impact on nearby communities." 49 U.S.C. § 47101(a)(2). Part of the FAA's mission, and therefore MDOT's mission, is to ensure that the communities surrounding airports are not hurt by noise from aircraft at airports. This mission is expressed in 49 U.S.C. § 47101(c), which states that "[i]t is in the public interest to recognize the effects of airport capacity expansion projects on aircraft noise. Efforts to increase capacity through any means can have an impact on surrounding communities. Noncompatible land uses around airports must be reduced and efforts to mitigate noise must be given a high priority." Thus, if noncompatible land uses around airports cannot be reduced, then the capacity of nearby airports should not be increased or else the FAA and the airport sponsor would violate federal law. ARB and MDOT seem aware that increases in capacity at the airport will affect the noise levels in Pittsfield, because they studiously have avoided the topic.

MDOT, as the agent of the FAA, must protect residents and property owners from the deleterious effects of aircraft noise. Federal law establishes the absolute duty of the government to protect both people and property from aircraft noise. "[T]he Congress declares that it is the policy of the United States to promote an environment for all Americans free from noise that jeopardizes their health or welfare." 42 USC § 4901(b). MDOT's statutory duty to protect people and property on the ground from the deleterious effects of aircraft noise goes beyond its duty under NEPA to determine what it believes to be "significant" or "reportable" under FAA Order 1050.1F. Legally speaking, the MDOT cannot conclude that a proposed MDOT action purportedly not "reportable" under 1050.1F, § 14.5e[6] or that purportedly does not have a "significant impact" under 1050.1F, § 14.3[7], is not subject to review and regulation under 42 USC § 4901(b), 49 U.S.C. § 40103(b)(2) and 49 U.S.C. § 44715(a)(1)(A). Those statutory obligations require that the lead agency address aircraft noise separate from its duties under NEPA because the lead agency's proposed action will create aircraft noise that will have a deleterious effect on the public health and welfare.

2. ARB and MDOT incorrectly assume that extending the runway will not increase the number of air operations, the fleet mix or other growth-inducing effects of the Project.

When considering an airport project for federal funding, the FAA must evaluate not merely the direct impacts of a project, but also its indirect impacts, including those "caused by the action and later in time but still reasonably foreseeable." 40 C.F.R. § 1508.8(b). Indirect impacts include a project's growth-inducing effects, such as changes in patterns of land use and population distribution associated with the project (40 C.F.R. § 1508.8(b)). It is reasonably foreseeable that the fleet mix at ARB will change for a higher percentage of jet operations as compared to the current level of light single and multi-engine propeller driven aircraft operations. The smaller Category A-I/II and B-I aircraft account for most of ARB operations. B-II and larger category aircraft account for a low percentage of ARB operations. If a longer runway became available, it is reasonably foreseeable that the number of night operations will increase as the number of arrivals of longer-haul business jets often occur in the evening hours due to the longer time duration

---

[6] *See also* 1050.1F B-1.4, p.B-4.

[7] *See also* 1050.1F, Table 4-1, p.4-8 well as increased population, increased traffic, and increased demand for services. *City of Davis v. Coleman*, 521 F.2d 661, 675 (9th Cir. 1975). The "growth-inducing effects of [an] airport project appear to be its *raison d'etre*." *California v. U.S. D.O.T.*, 260 F.Supp.2d at 978, citing *City of Davis, supra*, 521 F.2d at 675. Even though the Project is virtually defined by its growth- inducing impacts, ARB and MDOT have ignored this requirement completely not only in the draft EA, but in the public participation aspects of the Project as well.

of their trips. This is not merely an indirect, but also a direct effect, that the Project will have on the surrounding community. This will also affect the fleet mix of night operations to reflect a higher percentage of jet operations than exist under current conditions.

The runway need not be extended for most of ARB's "critical aircraft" to operate at the airport without weight restrictions. For example, the "load restrictions" will apply to the higher category aircraft (jets in the C-I and C-II categories). Operationally, weight is reduced by carrying fewer passengers, less baggage and/or less fuel, which discourage these aircraft from conducting operations at ARB. A Cessna Citation II (Category B-II), for example, requires 2,990 feet for takeoff at maximum certificated gross weight on a standard day, and, most days, can operate at unrestricted weight from ARB's existing 3,505-foot runway. A Lear 35 (Category C-I), requires 5,000 feet for takeoff at maximum certificated gross weight on a standard day. While extending the runway to 4,300 feet would not facilitate unrestricted operations by the Lear 35, the required weight reduction would be less than is currently required. Therefore, the runway extension to 4,300 feet would operationally benefit the Category C-I Lear 35, but would provide little or no operational benefit to the Category B-II Citation jet. Thus, while the runway extension makes ARB no more attractive to the operator of the Citation II, ARB becomes more attractive to the operator of the Lear 35, causing an increase in usage of ARB by the Lear 35, but the same usage by the Citation II. If the runway is extended there will be an increase in operations. Because there is a potential of an increase in the number of operations, it must be analyzed thoroughly.

The evidence is clear that the Project will cause an increase in both jet and night operations. It is also reasonably foreseeable these added high-performance jet aircraft operations and night operations will come with significant noise and air quality impacts. These reasonably foreseeable impacts must be analyzed in any future environmental assessment.

IV. Potential Mitigation/Permitting Requirements for Project Implementation.

A. Extending the Runway may require permitting from Pittsfield Township

As explained above, Pittsfield Township is considering not renewing the agreement between itself and the City of Ann Arbor that mandates the use of Ann Arbor's construction and electrical codes at the Airport. If the Airport moves forward with the extension of the runway, Pittsfield Township will consider not renewing the Agreement, which would terminate the Agreement on October 1, 2019. After that date, the Airport becomes subject to all of Pittsfield's ordinances, codes and planning requirements. In addition, Pittsfield Township is considering an ordinance that would require airports within its jurisdiction to receive approval of the Township Board before extending any runway at the airport.

B. The Environmental Assessment Must Account for the Effect the Project Will Have on Water Resources in the Surrounding Communities.

The Airport is the location of a porous sand/gravel formation that yields much water for pumping. Historically, the land where the airport is located was originally acquired by the City of Ann Arbor for water rights in 1921. Until recently, 15% of Ann Arbor's water supply came from the three wells on Airport property. The paving that the Project will require increases not only the impervious area on top of the aquifer, but also increases the risk of contamination. This reduces the infiltration of water that feeds the aquifer/City water supply. Adding 950 feet to the end of the runway adds another 71,250 square feet of impervious area over an aquifer vital to the City.

So critical is drinking water from the airport wells to the city that de-icing is prohibited on the airport. Due to the 'unmaintained nature' of the airport vegetation, it is acting as a buffer around the wellheads," the water faces many potential threats from a lengthened runway. Those threats become more critical because of the potential for lead to contaminate Ann Arbor's water supply. Most of the fuel utilized at ARB is consumed by piston-driven aircraft, which mostly use leaded AvGas. Any risk to the aquifer underlying the airport could pose a threat of lead contamination. With Ann Arbor's other water resources affected by dioxane risks caused by the "Gelman spill," the Airport well-field has taken on a much more significant role.

As FAA Order 1050.1F points out "[i]f there is the potential for contamination of an aquifer designated by the [EPA] as a *sole or principal drinking water resource* for the area, the responsible FAA official needs to consult with the EPA regional office, as required by section 1424(e) of the Safe Drinking Water Act, as amended." FAA Order 1050.1F, p.4-12 (emphasis added). Likewise, "[w]hen the thresholds indicate that the potential exists for significant water quality impacts, additional analysis in consultation with State or Federal agencies responsible for protecting water quality will be necessary. *Id.*, pp. A-75, A-76, & 17.4a. Finally, in situations such as this, "[i]f the EA and early consultation [with the EPA] show that there is a potential for exceeding water quality standards [or] identify water quality problems that cannot be avoided or mitigated . . . an EIS may be required." *Id.*, pp. A-75, & 17.3.

Because the wells on ARB property are a principal source of Ann Arbor's water supply, the Washtenaw County Water Resources Commissioner – another entity with whom ARB and MDOT should have been consulting from the very beginning – raised serious issues about the Project. In response to the draft EA, the Washtenaw County Water Resources Commissioner pointed out that:

> The amount of impervious surface on site would increase slightly due to the extension of the runway and taxiway from the existing 7 percent of the 837 acres to 7.4 percent. This slight increase noted equates to an additional 3.348 acres or

> 145,839 square feet. This increase in impervious surface this office considers significant and not slight knowing that the additional runoff from this area will discharge to the Wood Outlet Drain.

Besides the dioxane contamination, water resources issues at the Airport have become even more important after it was reported in May 2012, that the water table in the Ann Arbor area, has risen substantially. In the Ann Arbor Chronicle, "[t]he only hard data that the city has collected on the water table is at the municipal airport, and there the water table measures between 2-7 feet below the surface now, compared to 15 feet below the surface 50 years ago." This is not an insubstantial problem. With the water table at the airport now being 2-7 feet below the ground surface instead of 15 feet, when the drinking water wells were first dug, the groundwater is even more vulnerable to contamination because there is much less soil for any surface pollution to filter through or attach to soil particles before it reaches the water table. This dramatic change in the water table may also alter ground water data from the past. The rise in the water table may have altered the direction of groundwater flow, or there may now be some barrier blocking the traditional pathway for the water to flow, which would cause Ann Arbor's principal drinking water supply to be contaminated.

ARB has a responsibility under the law to ensure the safety of the water in Ann Arbor's wells. Further, although Pittsfield Township does not receive its drinking water from these wells, water from the same aquifer filling these wells is the source of water for numerous Pittsfield Township waterways, including the several ponds in the Stonebridge Community. Thus, beyond ensuring the Airport's compliance with the law, Pittsfield Township and its citizens have a vested interest in ensuring the water in the aquifer be maintained to the highest possible quality level. The EA must contain a comprehensive analysis of the water quality issues, and close participation of the various water quality agencies at the local, state and federal levels.

C. Air Quality Laws and Regulations Must Be Followed.

United States federal law states at 49 U.S.C. § 47101(a)(6) that it is "the policy of the United States - - that airport development under this subchapter provide for the protection and enhancement of natural resources and the quality of the environment of the United States." The Project will have a significant impact on the environment not only on the airport, but throughout the surrounding community. Since it is Pittsfield Township's duty and responsibility to protect the environment within its boundaries and protect its citizens from significant environmental impacts, it has serious concerns about the environmental impact the Project will have on the community.

Section 7506 of the Federal Clean Air Act (42 U.S.C. § 7401 et seq.) mandates that "[n]o department, agency, or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve, any activity which does not conform to [a State Implementation Plan] after it has been approved or promulgated under [42 U.S.C. §7410].” The Environmental Protection Agency (EPA) has promulgated regulations implementing § 7506 (the “Conformity Provision”) in 40 C.F.R. § 93.150 *et seq*. (“General Conformity Rule”). The General Conformity Rule requires, in part, that federal agencies first determine if a project is exempt from conformity analysis or presumed to conform. If it is neither, the agency must conduct a conformity applicability analysis to determine if a full conformity determination is required. *See Air Quality Procedures for Civilian Airports and Air Force Bases*, p. 13.

The project area, *i.e.*, Washtenaw County, is in attainment for five of the eight criteria pollutants, and maintenance for Ozone, PM_{10} and $PM_{2.5}$. A conformity determination is required for criteria pollutants in maintenance areas. 40 C.F.R. § 93.153(b). Therefore, the EA must show that one of the following applies: (1) the project is exempt from conformity; (2) the project is presumed to conform; or (3) the agency must conduct a conformity applicability analysis to determine if a conformity determination for Ozone, PM10 and $PM_{2.5}$ is required.

D. Risk of Canada Geese strikes requires Wildlife Hazard Assessment be drafted.

The risks to the Airport because of large numbers of Canada geese surrounding ARB, would become an even greater risk given the larger number of jets attracted to a lengthened runway. Our comments to the 2010 DEA raised the risk of the large number of Canada geese and provided photographic evidence to support the claim. FAA Advisory Circular 150/5200-33B discusses Hazardous and Protected Wildlife Attractants on or Near Airports and ranks geese as No. 3 in causing damage to aircraft. It discusses how golf courses, such as the one within 1,500 feet of the proposed expanded runway end, are attractive to Canada geese. This alone, with the two large ponds at Stonebridge, is one reason for the continued sightings of large numbers of Canada geese on the flightpaths of ARB. And the potential risks these Canada geese could cause, especially if many jets are attracted to a lengthened runway at ARB, underscore the urgency of conducting such a Wildlife Hazard Assessment as part of any environmental assessment. A lengthened runway will put the aircraft lower and closer to the areas where Canada geese congregate.

Further, the Migratory Bird Act of 1918 (16 U.S.C. § 703-712) makes it illegal to kill a Canada goose or harm their nests or eggs. So, Canada geese not only pose a potential risk of causing an aviation accident, but they are also protected, causing a dual concern to the Airport. This is compounded by the fact that mute swans, a species even larger than Canada geese, also inhabit the Stonebridge area just west of ARB, and could pose a further accident risk. A Wildlife Hazard Assessment must be completed before the proposed runway expansion project can move forward.

The documented risk from Canada geese and mute Swans requires a Wildlife Hazard Management Assessment. 14 C.F.R. § 139.337(b)(4) specifies that such an assessment must be conducted *immediately* when these events occurs on or near the airport:

> (4) Wildlife of a size, or in numbers, capable of causing an event described in paragraphs (b)(1), (b)(2), or (b)(3) of this section is observed to have access to any airport flight pattern or aircraft flight pattern or aircraft movement area.

14 C.F.R. § 139.337(b)(4). The "events described in paragraphs (b)(1) – (3)" are wildlife strikes, engine ingestion of wildlife, and/or substantial damage to aircraft from striking wildlife. Further, that completed Wildlife Hazard Management Assessment must be submitted to, evaluated, and approved by the FAA administrator before any further action on the proposed project can proceed. 14 C.F.R. § 139.337(e)(2).

V. CONCLUSION

There is no purpose or need for an extension of the runway at Ann Arbor Municipal Airport. Moreover, with residential neighborhoods to the south and west of the Airport, it would seem that extending a runway *toward* a heavily residential neighborhood makes little sense. It makes even less sense when one considers the fact that an airport capable of handling the larger, faster aircraft that ARB seeks to attract is a short 12 miles away. And then if one adds the fact that the surrounding communities have been, and continue to be, opposed to the extension of the runway for social, economic and environmental reasons, only then can one begin to grasp the hubris of the Airport to propose, yet again, the extension of the runway at ARB. When the environmental assessment is drafted, these issues must be addressed, or the environmental assessment will be incomplete. Pittsfield Township's position has not changed – the runway should not be extended at Ann Arbor Municipal Airport.

Sincerely,

Mandy Grewal, Ph.D.
Supervisor of Pittsfield Charter Township

Exhibit A

Chapter 14 **Offenses and Miscellaneous Provisions**

Article VIII **Noise Offenses**

[Adopted 2-25-2015 by Ord. No. 317 as Ch. 14, Art. VIII, of the 2015 Pittsfield Charter Township Code]

§ 14-34 **Noise general prohibition.**

It shall be unlawful for any person to create, assist in creating, permit, continue, or permit the continuance of any unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace or safety of others within the limits of the Township.

§ 14-35 **Specific acts prohibited.**

The following acts are declared unreasonably loud, disturbing, or unnecessary noises and are unlawful and prohibited, but this enumeration shall not be deemed to be exclusive:

A. The playing of any radio, phonograph, tape recorder, stereo, musical instrument or any sound amplification device of any character in such a manner or with such volume, at any time or place as to annoy or disturb the quiet, comfort or repose of persons in any office, dwelling, hotel or other type of residence or of any person in the vicinity.

B. The discharge into the open air of exhaust of any steam engine, compressed air machine, stationary internal combustion engine, motor vehicle, or any other machine, except through a muffler or other device that will effectively prevent loud or explosive or disturbing noises.

C. The creation of a loud unnecessary noise in connection with the loading or unloading of any vehicle or the opening and closing or destruction of bales, boxes, crates or their containers.

D. Yelling, shouting, whistling, loud talking or singing on the public streets, particularly between the hours of 10:00 p.m. and 7:00 a.m., or at any other time or place as to annoy or disturb the quiet comfort or repose of persons in any office, dwelling, hotel or any other type of residence or of any persons in the vicinity.

E. The use of any drums, loudspeakers, musical devices, or other instruments or devices for the purpose of attracting attention by the creation of noise to any performance, show or sale or display of merchandise.

F. The use of mechanical loudspeakers, on or from motor vehicles in a manner that causes the sound emitted from the vehicle to be heard on private property, except when a specific permit is first granted by the Township Board of Trustees. The Township Board of Trustees shall cause such a permit be issued when it finds the following:

- **(1)** The applicant has a noncommercial message that cannot be effectively communicated to the public by any other means of communication available.
- **(2)** The applicant will limit the use of the loudspeakers to times, locations and sound levels that will not unreasonably disturb the public peace.
- **(3)** The applicant will not use such equipment in residential areas between 6:00 p.m. and 9:00 a.m.

G. Construction, repair, erection, excavation, demolition, alteration or remodeling at any time on Sunday and between 8:00 p.m. and 7:00 a.m., Monday through Saturday, except in case of urgent necessity in the interest of public safety and then only upon permission having been first obtained from the Department of Building Services or the Department of Utilities and Municipal Services.

H. The firing of firearms, air guns, or other combustible substances for the purpose of making a noise or disturbance.

I. The practicing and training of any drum corps, band, orchestra or other musical organization, or the practice by individuals on the various musical instruments, that produce a noise or disturbance, and which annoy the peace, repose and comfort of the residents in the vicinity.

J. The excessive sounding of any horn or signal device, emanating from a motor vehicle, so as to create any loud or harsh sound plainly audible within any dwelling unit or residence, except as a warning of danger signal or an alert. As used in this subsection, "motor vehicle" means any vehicle that is self-propelled.

K. The playing or operation of any device designed for sound reproduction, including, but not limited to, any radio, television set, musical instrument, audio system, including cassette tape players, compact disc players, MP3 players, and speakers, or loud speaker in such a manner or with such volume as to be plainly audible in any dwelling unit or residence which is not the source of the sound, or to operate any such device on public property or on a public right-of-way so as to be plainly audible 50 feet or more from such device.

§ 14-36 **Registered owner of motor vehicle responsible for noise violations.**

In a prosecution for a violation of this article, proof that the particular motor vehicle described in the citation, complaint, or warrant was used in the violation, together with proof that the defendant named in the citation, complaint or warrant was the registered owner of the motor vehicle at the time of the violation, constitutes in evidence a presumption that the registered owner of the motor vehicle was the person who operated or controlled the motor vehicle when the noise violation occurred. The person in whose name the motor vehicle is registered with the Secretary of State is presumed to be the registered owner of the motor vehicle.

Exhibit B

Council unanimously agreed with Councilmember Morris to amend Paragraph A of Section I (Annexation - General) of the policy agreement as follows:

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the ~~centerline~~ SOUTH LINE of Ellsworth Road from U.S. 23 to the west line of ~~Platt~~ STATE Road, ~~thence southerly to the Railroad right-of-way adjacent to the City Landfill; thence westerly along the landfill line extended to Stone School Road, thence northerly along the east line of Stone School Road to the south line of Ellsworth Road; thence westerly to the west line of State Street,~~ thence northerly to the south line of I-94,...

The question being the Resolution with the amended Policy Agreement.

On a voice vote, Chair declared the motion carried unanimously.

The Resolution as adopted reads as follows:

R-280-7-78

RESOLUTION TO APPROVE CITY OF ANN ARBOR AND PITTSFIELD TOWNSHIP AGREEMENT

WHEREAS, the City of Ann Arbor officials and Pittsfield Township officials have spent many months negotiating an agreement of understanding; and,

WHEREAS, both governments agree to the principle of cooperation and not confrontation; and,

WHEREAS, the agreement is deemed in the best interests of the citizens of both units of government;

NOW, THEREFORE, BE IT RESOLVED that the following agreement of understanding be approved.

CITY OF ANN ARBOR–CHARTER TOWNSHIP OF PITTSFIELD POSITION PAPER ON PROMULGATION OF POLICIES

Promulgation of Policies

The CITY OF ANN ARBOR "The City", and the CHARTER TOWNSHIP OF PITTSFIELD, "The Township", by their respective governing bodies, for the purpose of furthering their common welfare, do hereby promulgate certain policies, and declare their intentions to abide the same in their exercise of governmental authority so far as practical and not in conflict with law.

I–ANNEXATION–GENERAL

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the south line of Ellsworth Road from U.S. 23 to the west line of State Road, thence

northerly to the south line of I-94, thence westerly to the western boundary of The Township, shall be designated as "The Territory" and shall be eventually annexed to the City in an orderly manner.

B. It shall be understood that this aforementioned line is the unofficial boundary line until such times it can be so officially designated.

C. Inasmuch as the Township and the City have an existing contract for sewer service for portions of the Township, the Township shall not make plans to provide municipal sewer and/or water service to any properties within said Territory, however the Township shall maintain all other legal authority and responsibility for Township lands and residents in the Territory until such time as they do become annexed to the City.

D. Notwithstanding previous policies, decisions and procedures, the City and Township hereby agree that individual properties in the designated area may be annexed to the City even where such annexation may create new islands. Neither the City nor the Township shall interpose in any judicial or other proceeding pertaining to the annexation of any portion of the said Territory an objection to such annexation by reason that the same would create an enclave of Township land within the City.

E. Neither the City nor the Township shall seek to require annexation to the City of any such enclave of Township land lying within the Territory, solely because of its constituting an enclave, whether now existing or hereafter created through the annexation of a portion of the Territory. Nevertheless, upon request to the City by the owner of a property within any said enclave for City water and/or sewer service to such property, the City may require such property to become annexed to the City as a condition of granting such service.

F. The Township agrees that rather than furthering litigation in the case of the Pittsfield Islands, it will agree to the Boundary Commission decision of 1973 (File No. 8322) if the individual review procedure as set forth in paragraph I-H is applied.

G. Through joint resolutions of the City and Township governing bodies any portion of the Territory within the designated area may be annexed to the City upon the petition therefor signed by the petitioners as provided by MCLA 117.9(8) in the case of such alternate method of annexation.

H. Upon annexation to the City of properties within said Territory the City "deferred charges" thereon, for benefits conferred by capital improvements made prior to the annexation shall be payable at the property owners option, either in full, or in not

less than six (6) equal annual installments, provided that the same shall be payable in up to twelve (12) equal annual installments in cases of a property being, and continuing to be, the homestead of an owner occupant who has special hardship problems or is otherwise adjudged in need of special consideration. Hardship and special considerations may be conferred upon the single owner occupant at time of annexation. A transition appeals committee shall be established for the purpose of determining such need. It shall be authorized to make recommendations to City Council for special consideration and shall be comprised of two (2) members appointed from the City and one (1) member appointed from the Township.

II–MUNICIPAL AIRPORT

A. The City agrees that the pending appeal of the decision of the Washtenaw Circuit Court in the suit of the Township vs. the City (Docket No. 77-12619) respecting the City's proceedings to annex Territories in and about the Municipal Airport and a portion of Eisenhower Boulevard shall be dismissed.

B. The Township agrees to cooperate with the City in the establishment of an Airport Land Use Plan which recognizes the compatibility of light industrial, warehousing, gravel mining and other uses on airport lands. The Township will review and comment on the plan before City adoption. It is further understood that any private construction on Airport lands will require approval under Township zoning and site plan requirements, as well as Township Building and Safety Department permit requirements. Plans for municipal construction on Airport lands must be submitted to the Township for review and comment.

C. The Township agrees to establish a land use plan for the environs of the Airport which recognizes only land uses which are compatible to airport operations from a safety and environmental point of view. The City will review and comment on the plan before adoption by the Township.

D. It is further agreed that gravel mining may take place only for use on City of Ann Arbor roads and public works projects and for use on Pittsfield Township roads, and public works projects. In addition, that a gravel processing plan, a restoration plan and a soil erosion plan be filed and reviewed by the Township.

E. Excepting as exempt by law, the Township shall assess for taxes the real and personal properties of and upon the airport lands.

F. The Township agrees to provide right-of-way for City sanitary sewage mains to the Airport to serve Airport properties uses only.

III–LANDFILL

A. The City desires to expand its Landfill operations to the west on property known as the Derck, Nielsen, and McCalla parcels.

B. The Township agrees to actively support and assist in acquisition negotiations such expansion on the conditions that:

1. A land use and restoration plan be developed for long range use of the landfill area.

2. That a reasonable strip of land immediately east of Stone School Road, as well as along Ellsworth Road, as well as along the northern edge of what is known as the Morgan properties is excluded for environmental purposes.

C. A Landfill Expansion Advisory Committee composed of four (4) persons appointed by the City and three (3) persons appointed by the Township shall be created to advise the City on environmental and operational plans.

D. The Township desires that it be given preferred customer consideration by the City in the use of the Landfill or offered an opportunity for proportionate investment equity if the Landfill is to be expanded in this location.

E. The Township shall not adopt any ordinance, rule or regulation which regulates or attempts to regulate the City's use of the landfill property so long as that property is used for disposal of refuse materials or for park purposes.

IV–SEWER/WATER SERVICEES

A. Upon acceptance and execution of this position paper, the City agrees to immediately approve the Township's request for sewer service limited to the Township Hall and the State Road frontage of a proposed commercial development at Ellsworth and State Roads in accordance with procedures established in Paragraph I-A of the Ann Arbor Pittsfield Sewer Service Agreement dated September 30, 1975. It is understood State Department of Natural Resources approval will be sought eagerly by the City.

B. The sewer service will be provided at 103% of City rates in accordance with the aforementioned agreement.

C. The City will agree to consider additional requests for service prior to the completion of the new "area wide treatment plant" on a case by case basis.

COMMUNICATIONS FROM THE MAYOR

Mayor Louis D. Belcher informed Councilmembers that he will be communicating with Mr. Robert Lillie, Pittsfield Township Supervisor, to advise him of the changes made tonight in the Pittsfield Township Agreement.

* *

Mayor Belcher alerted Council that there are several major Planning matters comming up for consideration, such as the eighty acres of land to be developed in the Briarwood area and a proposal for downtown housing.

* *

Mayor Belcher recommended the appointment of Hugh M. Wanty, 2061 Pauline Boulevard, to the Housing Board of Appeals to replace James J. O'Kane for an indefinite term.

Moved by Councilmember Trowbridge that Council concur in the recommendation of the Mayor.

On roll call the vote was as follows: Yeas, Councilmembers Latta, Greenberg, Morris, Senunas, Sheldon, Trowbridge, Cmejrek, Mayor Belcher, 8

Nays, 0

Councilmember Bell was absent from the Council Chamber at the time the vote was taken.

Chair declared the motion carried.

* *

Mayor Belcher recommended the appointment of Roberta Lea Shrope, 321 South Revena Boulevard, to the Planning Commission, effective July 1, 1978 for a three year term ending June 30, 1981.

Moved by Councilmember Cmejrek that Council concur in the recommendation of the Mayor.

On roll call the vote was as follows: Yeas, Councilmembers Senunas, Sheldon, Trowbridge, Cmejrek, Bell, Mayor Belcher, 6

Nays, Councilmembers Latta, Greenberg, Morris, 3

Chair declared the motion carried.

* *

Mayor Belcher laid the nomination on the table of Charles T. Wagner, 3425 Brentwood Court, to the Planning Commission to be confirmed at the next session of Council.

COMMUNICATIONS FROM COUNCIL COMMITTEES

None.

Exhibit C

AGREEMENT SUPPLEMENTING 1979 POLICY STATEMENT RELATIVE TO AIRPORT LAYOUT PLANS, AERONAUTICAL FACILITIES AND NON-AERONAUTICAL FACILITIES AT THE ANN ARBOR AIRPORT

This agreement ("Agreement") is between the City of Ann Arbor ("Ann Arbor"), a Michigan Municipal Corporation and Pittsfield Charter Township ("Pittsfield"), a Michigan Municipal Corporation.

RECITALS:

Ann Arbor owns and operates the Ann Arbor Airport ("Airport"), which is located in Pittsfield Charter Township.

In 1979 Pittsfield and Ann Arbor entered into an agreement entitled "Policy Statement," a portion of which has addressed certain aspects of the operation of the Ann Arbor Airport.

This Agreement is not intended to replace the Policy Statement. However, in the event of any conflict with the Policy Statement, this agreement shall apply.

Under the Michigan Aeronautics Code, MCL 259.1 et seq., Ann Arbor has jurisdictional control for the management, governance and use of the Airport, including application of its police powers, rules, regulations and ordinances, and including the zoning and planning of aeronautical facilities on the Airport property.

The City of Ann Arbor has adopted its construction code, including the building code, electrical code and mechanical code components thereof, in accordance with the Stille-DeRossett-Hale Single State Construction Code Act (MCL 125.1501 et seq.) ("construction code"). The City and the Township do not agree as to the authority granted to the City by the Michigan Aeronautics Code to extend and enforce its construction code at the Airport relative to aeronautical facilities. However, without deciding the extent of the City's authority under the Michigan Aeronautics Code, the City and the Township agree that to the extent it may be necessary, this agreement is an agreement between two public agencies that constitutes an interlocal agreement for purposes of Sections 4 and 5 of the Urban Cooperation Act (MCL 124.504 and 124.505) and Subsection 8b(2) of the Stille-DeRossett-Hale Single State Construction Code Act (MCL 125.1508b(2)) by which the City and the Township agree that the City shall extend and enforce its construction code to all aeronautical facilities constructed on Airport property, including issuing permits, inspections and enforcement of violations.

The Airport is serviced in whole by Pittsfield sanitary sewer service and is serviced in part by Pittsfield water service.

Unless and until Ann Arbor or the Airport qualifies as an authorized public agency for the Airport under Section 9110 of Part 91, Soil Erosion and Sedimentation Control, of

the Natural Resources and Environmental Protection Act, MCL 324.9110, Pittsfield has jurisdiction over the Airport for soil erosion and sedimentation control.

Wherefore, the parties agree as follows:

1. "Aeronautical facilities" means Airport buildings, landing fields and other facilities that are used for and serve aeronautical or aeronautically related operations and purposes. Aeronautical facilities include both facilities constructed by Ann Arbor and facilities that are privately constructed.

2. "Non-aeronautical facilities" means facilities whose use is unrelated to aeronautical operations or purposes.

3. A modification of the Airport Layout Plan is a land use plan as used in Section II.B. of the Policy Statement.

4. If a modification of the Airport Layout Plan is proposed, Ann Arbor will give notice to Pittsfield's Building Official or such other person as Pittsfield designates in writing, of the intent to modify the Airport layout plan at least 30 days before authorizing a professional services agreement for the modification. At least 30 days before submitting a modification of the Airport Layout Plan for approval by the Michigan Aeronautics Commission or the Federal Aviation Administration, Ann Arbor will provide Pittsfield's Building Official with copies of the documents to be submitted to those bodies. After approval of a modified Airport Layout Plan by the Michigan Aeronautics Commission or the Federal Aviation Administration, Ann Arbor will provide Pittsfield's Building Official with a copy of the proposed modification at least 30 days before the Ann Arbor City Council meeting at which it is to be submitted for approval.

5. Annually Ann Arbor will provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with a copy of the five year Airport Improvement Plan for the Airport.

6. If Ann Arbor applies for grant funds for new or expanded facilities shown or listed on the Airport Layout Plan or Airport Improvement Plan it will notify Pittsfield's Building Official, or such other person as Pittsfield designates in writing, of the application.

7. Aeronautical facilities being constructed at the Ann Arbor Airport are not required to go through the Pittsfield site plan review and approval process. However, when civil construction drawings for a project have been completed, but prior to bid for construction of the facilities, Ann Arbor will submit copies of the civil construction drawings to Pittsfield's Building Official, or such other person as Pittsfield designates in writing, for review and comment. The plans submitted to Pittsfield shall consist of four (4) sets of full sized drawings and a description of

the type of project, the general scope and the time frame. All proposed utilities associated with civil construction drawings for a project shall meet all current Township Land Development Standards.

8. Typical administrative fees will not be charged for the review of the plans submitted pursuant to paragraph 7, but the City will be responsible for establishing an Airport Plan (AP) escrow account for costs, which Pittsfield agrees shall be limited to its actual costs for plan review and comment.

9. Pittsfield will provide a written evaluation of the plans specified in paragraph 7 based on the Pittsfield Zoning Ordinance and Land Development Standards to Ann Arbor's Fleet & Facilities Manager, or such other person as Ann Arbor designates in writing, within two (2) weeks of the submittal in order to permit Ann Arbor staff to consider its comments.

10. Ann Arbor will consider and endeavor to incorporate reasonable recommendations provided by Pittsfield.

11. Ann Arbor will obtain soil erosion and sedimentation control permits for the Airport from Pittsfield until such time as Ann Arbor or the Airport qualifies as an authorized public agency for the Airport under Section 9110 of Part 91, Soil Erosion and Sedimentation Control, of the Natural Resources and Environmental Protection Act, MCL 324.9110.

12. Ann Arbor will obtain Pittsfield utility permits as required by Pittsfield ordinance for connections to Pittsfield sanitary sewer or water lines.

13. Ann Arbor shall extend and enforce its construction code, including the building code, electrical code and mechanical code components thereof, to all aeronautical facilities constructed on Airport property and provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with copies of all construction permit documents including the application, the permit, inspection reports and any certificate of occupancy within thirty days of being issued or received.

14. Non-aeronautical facilities at the Airport will be required to comply with Pittsfield planning and zoning requirements and the Pittsfield construction code ordinance.

15. Nothing contained in this agreement shall be construed as limiting Pittsfield's authority to enforce the State Construction Code regarding any violations of that code for non-aeronautical facilities.

16. Nothing contained in this agreement shall exempt aeronautical facilities from being in compliance with the State Construction Code unless said facilities are under the jurisdiction of the Federal Aviation Administration.

17. Ann Arbor shall extend and enforce its fire prevention code to all aeronautical facilities located on Airport property and provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with copies of all fire inspection documents including fire alarm and detection systems and fire extinguishing system certification and test reports, and all required operational permits within thirty days of being issued or received.

18. This agreement shall be approved by the concurrent resolutions of the Ann Arbor City Council and Pittsfield Charter Township Board of Trustees.

19. This agreement shall take effect October 1, 2009 or after a copy has been filed with both the Washtenaw County Clerk and the Michigan Secretary of State, whichever is later.

20. This agreement shall have a term of 5 years beginning on October 1, 2009. It shall automatically renew for successive 5 year periods unless either party provides the other with written notice of non-renewal at least 60 days before the end of a term.

Exhibit D

PITTSFIELD CHARTER TOWNSHIP
WASHTENAW COUNTY, MICHIGAN
RES #09-23
RESOLUTION OPPOSING PROPOSED EXPANSION OF THE ANN ARBOR MUNICIPAL AIRPORT RUNWAY

MARCH 24, 2009

Minutes of a Regular Meeting of the Township Board of Pittsfield Charter Township, Washtenaw County, Michigan, held at the Township Administration Building located at 6201 W. Michigan Avenue, in said Township, on the 24th day of March, at 6:30 p.m.

Members Present: Grewal, Israel, Scribner, Ferguson, Hunt, Krone, Yi.
Members Absent: None.

The following preamble and resolution were offered by Member Scribner and supported by Member Ferguson.

WHEREAS, the Ann Arbor airport is under the jurisdiction of the City of Ann Arbor and operated by an independent Authority and the land is located within Pittsfield Charter Township immediately adjacent to a residential area; and

WHEREAS, the existing width and length has not posed any substantial safety concerns in the past with only five incidents of landing mishaps out of a total of 600,000 landings in the past eight years; and

WHEREAS, the proposed changes and expansion would shift the runway dangerously close to a busy township roadway (Lohr Road) and closer to dense residential subdivisions; and

WHEREAS, such a runway expansion will significantly increase air traffic volumes and noise pollution experienced by residential subdivisions in the vicinity of the Ann Arbor airport, thereby resulting in a decline of residential home property values; and

WHEREAS, the City of Ann Arbor has not fully demonstrated the economic and safety justifications for undertaking the proposed runway expansion; and

WHEREAS, the City of Ann Arbor appears to have not taken into consideration the negative safety implications such a runway expansion may impose on the surrounding residential subdivisions by expanding a runway closer to residential subdivisions

NOW THEREFORE BE IT RESOLVED, the Pittsfield Charter Township Board of Trustees urges the City of Ann Arbor to reconsider the merits of expanding the Ann Arbor Airport runway in light of the negative implications such an expansion would impose on the residents of Pittsfield Charter Township.

AYES: Grewal, Israel, Scribner, Ferguson, Hunt, Krone, Yi.
NAYS: None.
ABSENT: None.
ABSTAIN: None.

RESOLUTION DECLARED ADOPTED.

Alan Israel, Clerk
Pittsfield Charter Township

DATED: March 24, 2009.

CERTIFICATE

I, Alan Israel hereby certify that the foregoing is a true and complete copy of a resolution adopted by the Township Board of Pittsfield Charter Township, County of Washtenaw, State of Michigan, at a Regular Meeting held on March 24, 2009, and that said meeting was conducted and public notice of said meeting was given pursuant to and in full compliance with the Open Meetings Act, being Act 267, Public Acts of Michigan, 1976, and that the minutes of said meeting were kept and will be or have been made available as required by said Act.

Alan Israel

Alan Israel, Clerk
Pittsfield Charter Township

DATED: March 24, 2009.

Exhibit E

LODI TOWNSHIP
WASHTENAW COUNTY, MICHIGAN
RESOLUTION # 2009-009
A RESOLUTION OPPOSING PROPOSED RUNWAY EXPANSION OF THE ANN ARBOR MUNICIPAL AIRPORT

WHEREAS, the Ann Arbor airport is under the jurisdiction of the City of Ann Arbor and operated by an independent Authority and the land is located within Pittsfield Charter Township immediately adjacent to residential areas, including Lodi Township;

WHEREAS, the existing width and length of Runway 6-24 has not be posed any substantial safety concerns in the past with only five incidents of landing mishaps out of a total of 600,000 landings in the past eight years; and

WHEREAS, the proposed changes and expansion would shift the runway so that it ends a mere 700 yards from a busy roadway (Lohr Road) and closer to dense residential subdivisions; and

WHEREAS, such a runway will significantly accommodate larger and heavier aircraft, increase air traffic volumes, and increase noise pollution experienced by residential subdivisions in the vicinity of the Ann Arbor airport, thereby resulting in a decline in residential home property values; and

WHEREAS, the City of Ann Arbor has not fully demonstrated the economic and safety justifications for undertaking the proposed runway expansion; and

WHEREAS, the City of Ann Arbor appears to have not taken into consideration the negative safety implications such a runway expansion may impose on the surrounding residential subdivisions by expanding a runway closer to residential subdivisions;

NOW, THEREFORE BE IT RESOLVED, the Lodi Township Board of Trustees urge the City of Ann Arbor to reconsider the merits of expanding the Ann Arbor Airport runway in light of the negative implications such an expansion would impose on the residents of Lodi Township.

ROLL CALL VOTE:
Ayes: Masters, Staebler, Lindemann, Canham, Foley, and Godek.
Nays: Rentschler.
Absent: None.
Abstain: None.

RESOLUTION DECLARED ADOPTED

____
Elaine Masters, Clerk, Lodi Township
DATED: May 12, 2009

State Block Grant Program
Memorandum of Agreement
Between
The Federal Aviation Administration
Detroit Airports District Office
And
State of Michigan, Department of Transportation
Bureau of Aeronautics and Freight Services

A Memorandum of Agreement (hereinafter referred to as "MOA") by and between the Bureau of Aeronautics and Freight Services, representing the Michigan Department of Transportation (hereinafter referred to as "BAFS" and "MDOT") and the Detroit Airports District Office, representing the Federal Aviation Administration (hereinafter referred to as "DET-ADO" and "FAA") to implement FAA's State Block Grant Program (hereinafter referred to as "SBGP") to improve general aviation airports in Michigan.

WHEREAS, Title 49 USC §47128, authorizes the Federal Aviation Administration's (FAA's) current SBGP; FAA regulation 14 CFR, Part 156 discusses how FAA carries out the SBGP. FAA Order 5100.38, *Airport Improvement Program Handbook, paragraphs 1090-1099*, provides guidance for "...administering a block grant made under this section" (49 USC §47128(b) (1)), and

WHEREAS, MDOT was selected by the Federal Aviation Administration to manage federal airport aid funds for nonprimary airports included under the FAA SBGP, and

WHEREAS, This Memorandum of Agreement (MOA) effective as of the date signed by both parties will replace the previous agreement dated March 16, 1993, and

WHEREAS, in mutual agreement, MDOT and FAA document and execute these understandings and commitments in written form by representatives of each party.

NOW, THEREFORE, MDOT and FAA do attest to the following understandings and commitments with respect to the FAA SBGP:

1. **Term of this Agreement**

   Unless otherwise stipulated, the responsibility of MDOT in carrying out the terms of this agreement and the SBGP will begin with acceptance of this agreement and run concurrently with current funding authorization or 5 years, whichever occurs first.

   The FAA will issue MDOT a Block Grant yearly for each of the five fiscal years beginning the fiscal year following the execution of this agreement. The DET-ADO may issue additional Block Grants if circumstances require. Block Grant issuance will occur as soon as practicable after the FAA has received its budget authorization to issue AIP grants. Non-primary entitlement funds must be obligated within three (3) years and expended within four (4) years. No construction to be funded with AIP Discretionary funds can start prior to the FAA awarding the SBG containing those funds.

The DET-ADO and MDOT will perform a review of this SBG agreement, within ninety (90) calendar days of any applicable legislative provision becoming law or regulatory provision taking effect, to determine the need for a new SBG agreement or amendment.

MDOT or FAA may elect to amend or terminate this agreement at the start of a new fiscal year with ninety (90) days prior written notice. MDOT also agrees that it will continue to administer SBGP projects placed under grant even though the final phases of administration and closeout of such projects may continue beyond the date MDOT no longer participates in the program.

2. **Airports Included**

The State will be responsible for monitoring project accomplishments at all airports covered by the SBGP to assure that all agreements and assurances with airport sponsors are met during the program, except that Part 139 requirements will continue to be FAA responsibilities where applicable.

Commercial service airports that change from primary to non-primary status will continue to be the responsibility of the FAA for three years. After three years, the airport will be included in the SBG and oversight transferred to MDOT. The DET-ADO will retain responsibility for administering and closing grants that were issued by the FAA. Airports within the SBG that change from non-primary to primary will be removed from subsequent SBG in the first fiscal year primary entitlements are available. MDOT will retain responsibility for administering grants issued while the subject airport was within the SBG. See Attachment A.

3. **Review**

Ongoing review of the Program by FAA is required by Title 49 USC § 47128. An advisory team comprised of DET-ADO representatives will conduct evaluations which may include visits to project sites and the MDOT offices. This review will include a yearly program evaluation, random periodic project reviews and general program administrative review. A summary report from MDOT may be required.

4. **Personnel**

MDOT shall maintain sufficiently qualified personnel to fulfill all of its professional, technical and administrative obligations under this MOA.

5. **Federal Regulations**

In carrying out this program, MDOT will comply with all Federal laws, regulations and executive orders set forth in Attachment B. MDOT also acknowledges awareness of FAA policy and guidance in the form of Orders which have applicability to the state block grant program and are set forth in Attachment B. The DET-ADO will provide advice, interpretation and guidance on any documents referenced in Attachments B and C.

6. **FAA Relationship to Block Grant sponsors and consultants**

The FAA will refer sponsors/consultants to MDOT to answer project specific questions on active and proposed block grant projects. In the event there is a dispute between the sponsor/consultant and MDOT, the parties may contact the FAA for advice. However, MDOT is ultimately responsible for project administration.

7. **Role of FAA**

DET-ADO shall serve as primary contact for MDOT on questions regarding policy, eligibility, and overall guidance.

8. **Land Use Zoning**

MDOT will assist airports in their efforts to protect against encroachment of incompatible land use. The State will assume a high-level of responsibility for helping airport sponsors establish zoning protection to safeguard the Federal investment in an airport.

9. **Runway Safety Area Determinations**

A runway safety area determination must be made prior to issuance of any subgrant under the SBGP for any project of runway construction, reconstruction, or significant expansion in accordance with FAA Order 5200.8, *Runway Safety Area Program*, current edition. Preferably, the RSA determination should be completed prior to the project being included in the CIP and ideally as part of the ALP approval process. The RSA determination should follow the format previously provided to MDOT by the DET-ADO. MDOT will prepare and sign those RSA determinations where the determination is that a) the existing RSA meets the current standards contained in FAA Advisory Circular 150/5300-13, *Airport Design*, or b) the existing RSA does not meet the current standards but it is practicable to improve the RSA so that it will meet current standards. Should the ADO disagree with any RSA determination prepared and signed by MDOT, the DET-ADO will discuss with MDOT the area(s) of disagreement and request that MDOT revise the determination. The DET-ADO retains the authority to modify and reissue any MDOT RSA determination. A copy of the RSA determinations issued by MDOT will be provided to the DET-ADO for database entry.

MDOT will provide a draft RSA determination to the DET-ADO where the proposed determination is that (1) the existing RSA can be improved to enhance safety, but the RSA will still not meet current standards, or (2) the existing RSA does not meet current standards, and it is not practicable to improve the RSA. The latter RSA determinations must be signed by the FAA Great Lakes Region's Airports Division Manager, therefore, the draft RSA determination should be provided to the DET-ADO at least 60 days prior to issuance of the applicable subgrant.

10. **Program Responsibilities**

Airport actions under the AIP that would normally be under FAA's scope become State actions under the SBGP. Attachment D contains a list of roles and associated responsibilities which serves as a nonexclusive guide of tasks to be performed under the SBGP. Revisions to this list will require agreement between the State and DET-ADO, as witnessed by the signature of their authorized representatives.

11. **Funds Control**

MDOT will establish rules to govern the co-mingling of AIP funds from multiple appropriation years, including both use and reporting of funds, as well as close-out process. Non-primary entitlement funds must be obligated within three (3) years and expended within four (4) years. MDOT will report to the DET-ADO on how the specified entitlement amounts were used at the end of four years after such block grant has been issued. If a subgrant for the non-primary entitlements is not issued within the four-year period, the funds will be considered excess and recovered by the DET-ADO.

12. **Capital Improvement Plan**

FAA Order 5100.39, *Airports Capital Improvement Plan (ACIP)*, outlines requirements to establish a capital improvement plan (CIP) as a rolling three-year planning document.

MDOT will work with the DET-ADO to update the CIP as required to accomplish SBGP programming. MDOT will use its own priority rating system for administration of apportionment and non-primary airport entitlement funds under the SBGP. If MDOT is pursuing discretionary funding for a project, MDOT will be required to clearly identify all phases of the project, proposed funding sources and types of funds. Discretionary fund planning ceilings for the SBG will be distributed to MDOT as soon as available to DET-ADO. MDOT will provide a current CIP, based on a three year rolling plan that is within the discretionary fund planning ceiling limitations established by DET-ADO for the associated funding years. Priority ranking of projects for each airport receiving funding will be included to assist FAA with overall planning and programming decisions related to the State of Michigan.

The updated CIP will be submitted to the DET-ADO by **December 15** of each calendar year, unless requested earlier. In the event that an alternative date is requested by the FAA for the CIP update, the DET-ADO will inform MDOT as soon as new deadlines are identified and become available to the DET-ADO. MDOT agrees to make every reasonable effort to meet an alternative date that is requested by the FAA.

A planning and financial plan will be required for any project that will depend on more than $5 million in Discretionary funds (in aggregate). This plan shall be submitted to the DET-ADO with the Discretionary request. MDOT will also prepare Benefit/Cost Analyses (BCAs) as required consistent with FAA policy.

13. **Reporting**

MDOT will provide quarterly status reports to the DET-ADO covering:

a) MDOT's current plan for spending Airport Improvement Program (AIP) state apportionment funds for past, current and future years (electronic spreadsheet format);
b) Grants received under the SBGP and subgrants awarded, clearly delineating funding sources by project, location, and funding year, and identifying any subsequent reimbursements planned (electronic spreadsheet format); and
c) Standard Form 272, Federal Cash Transactions Report.

14. **Limitations**

MDOT may not use SBGP funds to accomplish projects, which are not eligible under Title 49 USC, Chapter 471, as interpreted by the FAA, nor at airports, which are not eligible for grants under Title 49 USC, Chapter 471.

The SBG will include all non-primary airports within the State of Michigan, with the exception of Detroit-Willow Run Airport.

15. **Airport Sponsor Adherence to Standard Assurances**

Each recipient of federal funds under this program shall be required to adhere to the standard airport sponsors assurances as provided by FAA and such assurances shall be incorporated into the terms and conditions of the subgrant agreement issued to the sponsor by MDOT.

16. **Project Completion**

All projects funded with AIP funds, particularly Discretionary funds, are expected to be completed expeditiously and properly phased to use the funds in a reasonable timeframe. Each project should result in usable units of work.

17. **Accounting and Audits**

MDOT must have an accounting method that accurately reflects expenditures of SBGP funds. All SBGP projects are subject to the same audit requirements as any other grant and must comply with Order 5100.38, as amended. These reporting and auditing requirements may be supplemented from time to time by FAA Headquarters or Regional policies in order to comply with new statutory requirements, including the Federal Financial Accountability and Transparency Act (FFATA).

18. **Construction Specifications**

The construction specifications used for projects under this program shall be those promulgated by FAA in the Advisory Circulars or such MDOT construction specification as pre-approved by FAA. Any project complying with either FAA or FAA-approved MDOT standards shall be deemed to meet federal standards for the purpose of future federally funded projects.

19. **Records Retention/Availability**

MDOT will provide status reports when sought by the FAA. MDOT will maintain files on the status and history of each project. These files will be available to the FAA at any reasonable time for their review. In addition, MDOT will provide DET-ADO with copies of each subgrant agreement when it is executed. MDOT will retain sub-grant project files with a process and time frame that meets or exceeds FAA requirements as outlined in FAA Order 1350.15, *Records Transfer and Destruction Standards.* MDOT will also make historical project documentation accessible to airport sponsors and consultants for use in subsequent planning and environmental processes.

20. **Site Selection**

MDOT will provide to the FAA, through the DET-ADO, a review and recommendation for approval of any site selection where federal funds or future inclusion in the NPIAS is anticipated.

21. **Airport Sponsor Required to have Approved Airport Layout Plan (ALP)**

No development project grant will be issued under this program unless the Sponsor has an approved Airport Layout Plan (ALP) depicting the proposed work.

Under the SBGP, MDOT must coordinate an ALP with all interested parties, including the FAA, and approve it. The ALP will be in accordance with the Great Lakes Region PPM 5310.1, FAA Advisory Circular 150/5070, *Airport Master Plans* and requirements promulgated by the DET ADO. MDOT will provide the DET ADO with one copy of the final approved ALP.

22. <u>Design Criteria</u>

The geometric and design standards used for projects under this program will be those promulgated by the FAA in the Advisory Circulars. Any request for a modification to standards must come to the DET ADO through MDOT with their review and recommendation for approval. Any request sent directly to the FAA by a sponsor or sponsor's consultant to modify standards for a state block grant project will be immediately referred to MDOT for their action.

23. <u>Environmental Responsibilities</u>

SBGP Projects

The DET-ADO reserves the right to review and comment, at its discretion, on any environmental document prepared for projects funded under the SBGP. MDOT agrees to consider and reconcile such comments.

Federal Actions Connected to SBGP Projects

When airport development actions are to be conducted outside the purview of the SBGP such projects are considered "Federal actions" and are subject to relevant FAA environmental analysis per requirements of FAA Orders 5050.4 and 1050.1. The actions listed below are not authorized under the SBGP and occur clearly outside of its scope. FAA organizations retain NEPA review responsibility for the following:

a) SBGP airport actions for which MDOT requests AIP discretionary funds to supplement SBGP funding for a specific airport project at a specific location and FAA anticipates providing those funds,
b) Airport noise compatibility planning, including approval of airport noise compatibility programs under 14 CFR Part 150,
c) Airport land releases, including approval of such releases,
d) Approval of an airport location (new airport),
e) Installing or moving FAA-owned navigational equipment,
f) Establishing or revising air traffic and flight procedures.

Environmental Document Preparation

Paragraph 23, items a-f, above, list those Federal actions that may be connected to airport actions that are funded under the SBGP. Because those connected Federal actions fall outside the SBGP they remain under the purview of an FAA organization and are subject to NEPA. In preparing environmental documents for SBGP projects and for those projects considered Federally-connected actions, MDOT shall cooperate with the responsible FAA organization as it prepares the necessary environmental document to address both the State "NEPA-like" requirements, as well as the Federal NEPA responsibilities. Environmental document processing for SBGP and Federal actions is explained in FAA Order 5050.4, Paragraph 214.

24. <u>Wildlife Management</u>

MDOT agrees to address hazardous wildlife attractant issues on or near airports, in accordance with Advisory Circular 150/5200-33, as follows:

a) On landfill proposals, the MDOT shall evaluate the proposal and forward its draft determination to the DET-ADO for concurrence. Following receipt of FAA concurrence, the MDOT shall send a letter to the proponent with the final determination.
b) On other proposals with land use practices that could potentially attract wildlife hazards, the MDOT shall evaluate the proposal and issue the determination to the proponent with a copy to the DET-ADO.

25. <u>Congressional Inquires</u>

Congressional inquiries about all matters concerning the SBGP will be referred to DET-ADO. MDOT will provide assistance as requested. The DET-ADO will respond to the congressional office. DET-ADO will copy MDOT on all congressional responses.

26. <u>Request for Release of Land</u>

MDOT shall be responsible for review of requests for release of airport land made by sponsors. Once MDOT has reviewed the land release requests, they will be submitted, along with MDOT's recommendation, to the DET-ADO for coordination and final approval. DET-ADO will consider MDOT's recommendation before making land release decisions.

27. **Letter of Credit Drawdowns**

Drawdown of federal funds will be by letter of credit referencing Block Grant number.

ATTACHMENT C

This attachment lists key provisions of applicable FAA Orders that should be incorporated by specific reference in the sate block grant agreement. The purpose is to ensure that block-grant states fully understand their legal obligations under the SBG program, and the FAA's oversight responsibilities in the various program areas.

1. FAA Order 5050.4B ("National Environmental Policy Act Implementing Instructions for Airport Projects"), with particular reference on Paragraph 210 ("The State Block Grant Program"). However, this paragraph includes references to the applicability of other requirements throughout the Order, based on Federal laws including but not limited to NEPA.

2. FAA Order 5100.38C ("Airport Improvement Program Handbook"), with particular reference to:

   - Chapter 1, Sections 1-3 which provide general background on the statutory provisions governing the Airport Improvement Program.
   - Chapter 10, Section 9 ("Block Grant Procedures"), with particular focus on Paragraphs 1090-1097.

3. FAA Order 5100.39A ("Airport Capital Improvement Plan"), particularly Paragraph 10 ("Use of Other Priority Systems").

4. FAA Order 5190.6A ("Airport Compliance Requirements"), particularly Chapter 3 ("Exclusive Rights") and Chapter 4 ("Obligations of Airport Owners").

ATTACHMENT D: PROGRAM RESPONSIBILITIES

Airport actions under the AIP that would normally be under FAA's scope become State actions under the SBGP. MDOT and FAA have program responsibility for airport actions, as described in the following Tables.

ADMINISTRATIVE RESPONSIBILIITES			
TASK/FUNCTION	STATE	FAA	COMMENTS
Airport (Non-primary Commercial Service)	X		
Airport (Reliever GA)	X		
Airport (Non-Reliever GA)	X		
Funding Privately Owned Airports-Approval	X		
Sponsor Eligibility	X		
Approve SBGP Funds for Airport Action	X		
Records Retention	X		3 years beyond financial completion of block grant
Facilities & Equipment (F&E) Budget Requests	X	X	Coordinate with ATO
Funds Control/Obligation Goals	X		
Congressional Inquiries	X		Copy of reply to DET-ADO
Civil Rights	X		Per Agreement with FAA Civil Rights Office

LAND RESPONSIBILITIES			
TASK/FUNCTION	STATE	FAA	COMMENTS
Appraisals	X		
Relocation	X		
Title Opinion	X		
Donated Land Value	X	X	Coordinate with DET-ADO
Property Interest Prior to Construction	X		
Exhibit A, Property Map Revision/ Update	X		

CONSTRUCTION RESPONSIBILITIES			
TASK/FUNCTION	STATE	FAA	COMMENTS
FAA Reimbursable Agreement	X	X	Coordinate with DET-ADO
Review Safety and Phasing Plan	X		

Construction Inspection –Interim	X		
Construction Inspection – Final	X		
Pre-Construction Conference	X		
User Coordination	X		
Change Orders	X		
Update FAA Form 5010	X		
Data for Approach Procedures	X	X	Submission in accordance with established timelines
As-Built Record Drawings	X		
Advertising for Bids	X		
Award to Low Bidder	X		
Reasonableness of Cost	X		
Non-AIP Separate Records	X		
Wage Rates	X		
EEO & Wage Rate Posters	X		
Bond Payment/Performance	X		
Construction Contracts	X		
Shutdown Schedule Coordination	X		
Contract for Utility Relocation	X		
Force Account Work Approval		X	Coordinate with DET-ADO for State Force Account Work
Debarment List	X		
No Work Prior to Federal Grant Execution	X		
Comply with Airspace	X		
Notice to Proceed	X		
Material Testing	X		
Construction Inspection Report	X		

PAYMENT RESPONSIBILITIES			
TASK/FUNCTION	**STATE**	**FAA**	**COMMENTS**
Payment via Letter of Credit	X		
Final Payments	X		
Partial Payments	X		No advance payments
Obligation Schedule	X		Submit to DET-ADO quarterly
Tracking Expenditures of Federal Funds	X		Submit to DET-ADO quarterly

AIRSPACE RESPONSIBILITIES			
TASK/FUNCTION	**STATE**	**FAA**	**COMMENTS**
Changes to Airport Layout Plan	X	X	Coordinated with DET-ADO, approved by MDOT.
Construction Equipment	X	X	Coordinated with DET-ADO,

			approved by MDOT.
Safety/Phasing Plan	X	X	Coordinated with DET-ADO, approved by MDOT.
Non-rule Making Actions (NRA) Studies	X	X	Coordinated with DET-ADO, approved by MDOT.
Local Airport Events	X	X	Coordinated with DET-ADO, approved by MDOT.

DESIGN RESPONSIBILITIES			
TASK/FUNCTION	STATE	FAA	COMMENTS
Pre-Design Meeting	X		
Plans/Spec. Review	X		
Plans/Spec. Certification	X		
Plans/Spec. Approval	X		
Relocation of NAVAIDs	X	X	Coordinate with DET-ADO to facilitate coordination with FAA ATO
Design Variance Approval/ Modification to Standards	X	X	MDOT submit request and recommendations to DET-ADO
Coordinate with State and Federal Highway Office	X		
Pavement Design/Materials	X		
Consultant Selection	X		
ARFF & Snow Removal Equipment Specs	X		Comply with Advisory Circular, no modifications

COMPLIANCE RESPONSIBILITIES			
TASK/FUNCTION	STATE	FAA	COMMENTS
Land Release	X	X	MDOT reviews proposal and requests FAA concurrence. FAA must approve.
Surplus Property Program		X	
Surplus Property Release	X	X	MDOT reviews proposal and request FAA concurrence. FAA must approve.
Sub-Grant Special Conditions	X		
Clear Approaches	X		
Compatible Land Use	X		
Landfills	X	X	Review proposal, FAA concurrence
GA Safety Inspections	X	X	FAA responsible for GA Part 139 airports.
Informal Complaints	X	X	MDOT responsible for

			investigation and resolution of informal complaints. If resolution unsuccessful, DET-ADO will assist and/or resolve.
Formal Complaints		X	
Compliance Determination FAA Order 5190.6A	X	X	Coordinate the DET-ADO

PLANNING RESPONSIBILITIES			
TASK/FUNCTION	**STATE**	**FAA**	**COMMENTS**
State System Plan update	X		Once every 5 years, at a minimum.
Determining Eligibility & Timing of Airport Actions	X		
National Environmental Policy Act (NEPA)	X	X	State – State Apportionment and Non-Primary Entitlement projects FAA – Discretionary projects
Public Coordination	X		
Planning Grants	X		
NPIAS Updates	X	X	Coordinate with DET-ADO
New NPIAS Site	X	X	MDOT request & provide rationale
Airport Layout Plan Approval	X		
Instrument Approach Procedures	X	X	Submission in accordance with established timelines
TASK/FUNCTION	**STATE**	**FAA**	**COMMENTS**
iOE/AAA Airport Data Base	X	X	MDOT inputs runway data.
Part 150		X	FAA – Part 150 Studies & Technical Assistance
Congressionally Mandated Projects	X	X	Projects must be funded or justification provided for not funding projects.
Executive Order 12372, Intergovernmental Review	X		
Zoning Ordinances	X		
Coordination with Local Councils of Governments or Other Appropriate Local Agencies	X		
Priority System	X	X	In conjunction with Regional guidance

ADDITIONAL RESPONSIBILITIES

The following reports/information is to be submitted to the DET-ADO by MDOT:

Reports/Submittals	Timing
Master Airport Sponsor Certification	Included in grant application
Grant expenditures & summary report	Quarterly & as requested
Copy of sub-grants	As issued
Copy of approved ALP's	Continuous
Copy of Congressional replies	Continuous
Compliance findings	Continuous
Summary reports	At Grant Closeout
NPIAS update	Continuous
Civil Rights report to AGL-9	If requested (State must have on file)
Terminal Area Forecast update	When requested

Chapter 14. Offenses and Miscellaneous Provisions

Article VIII. Noise Offenses

§ 14-34. Noise general prohibition.

It shall be unlawful for any person to create, assist in creating, permit, continue, or permit the continuance of any unreasonably loud, disturbing, unusual or unnecessary noise that either annoys, disturbs, injures or endangers the comfort, repose, health, peace or safety of others within the limits of the Township.

§ 14-35. Specific acts prohibited.

The following acts are declared unreasonably loud, disturbing, or unnecessary noises and are unlawful and prohibited, but this enumeration shall not be deemed to be exclusive:

A. The playing of any radio, phonograph, tape recorder, stereo, musical instrument or any sound amplification device of any character in such a manner or with such volume, at any time or place as to annoy or disturb the quiet, comfort or repose of persons in any office, dwelling, hotel or other type of residence or of any person in the vicinity.

B. The discharge into the open air of exhaust of any steam engine, compressed air machine, stationary internal combustion engine, motor vehicle, or any other machine, except through a muffler or other device that will effectively prevent loud or explosive or disturbing noises.

C. The creation of a loud unnecessary noise in connection with the loading or unloading of any vehicle or the opening and closing or destruction of bales, boxes, crates or their containers.

D. Yelling, shouting, whistling, loud talking or singing on the public streets, particularly between the hours of 10:00 p.m. and 7:00 a.m., or at any other time or place as to annoy or disturb the quiet comfort or repose of persons in any office, dwelling, hotel or any other type of residence or of any persons in the vicinity.

E. The use of any drums, loudspeakers, musical devices, or other instruments or devices for the purpose of attracting attention by the creation of noise to any performance, show or sale or display of merchandise.

F. The use of mechanical loudspeakers, on or from motor vehicles in a manner that causes the sound emitted from the vehicle to be heard on private property, except when a specific permit is first granted by the Township Board of Trustees. The Township Board of Trustees shall cause such a permit be issued when it finds the following:

   (1) The applicant has a noncommercial message that cannot be effectively communicated to the public by any other means of communication available.

   (2) The applicant will limit the use of the loudspeakers to times, locations and sound levels that will not unreasonably disturb the public peace.

(3) The applicant will not use such equipment in residential areas between 6:00 p.m. and 9:00 a.m.

G. Construction, repair, erection, excavation, demolition, alteration or remodeling at any time on Sunday and between 8:00 p.m. and 7:00 a.m., Monday through Saturday, except in case of urgent necessity in the interest of public safety and then only upon permission having been first obtained from the Department of Building Services or the Department of Utilities and Municipal Services.

H. The firing of firearms, air guns, or other combustible substances for the purpose of making a noise or disturbance.

I. The practicing and training of any drum corps, band, orchestra or other musical organization, or the practice by individuals on the various musical instruments, that produce a noise or disturbance, and which annoy the peace, repose and comfort of the residents in the vicinity.

J. The excessive sounding of any horn or signal device, emanating from a motor vehicle, so as to create any loud or harsh sound plainly audible within any dwelling unit or residence, except as a warning of danger signal or an alert. As used in this subsection, "motor vehicle" means any vehicle that is self-propelled.

K. The playing or operation of any device designed for sound reproduction, including, but not limited to, any radio, television set, musical instrument, audio system, including cassette tape players, compact disc players, MP3 players, and speakers, or loud speaker in such a manner or with such volume as to be plainly audible in any dwelling unit or residence which is not the source of the sound, or to operate any such device on public property or on a public right-of-way so as to be plainly audible 50 feet or more from such device.

Council unanimously agreed with Councilmember Morris to amend Paragraph A of Section I (Annexation - General) of the policy agreement as follows:

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the ~~centerline~~ SOUTH LINE of Ellsworth Road from U.S. 23 to the west line of ~~Platt~~ STATE Road, ~~thence southerly to the Railroad right-of-way adjacent to the City Landfill; thence westerly along the landfill line extended to Stone School Road, thence northerly along the east line of Stone School Road to the south line of Ellsworth Road; thence westerly to the west line of State Street,~~ thence northerly to the south line of I-94,...

The question being the Resolution with the amended Policy Agreement.

On a voice vote, Chair declared the motion carried unanimously.

The Resolution as adopted reads as follows:

R-280-7-78

RESOLUTION TO APPROVE CITY OF ANN ARBOR AND PITTSFIELD TOWNSHIP AGREEMENT

WHEREAS, the City of Ann Arbor officials and Pittsfield Township officials have spent many months negotiating an agreement of understanding; and,

WHEREAS, both governments agree to the principle of cooperation and not confrontation; and,

WHEREAS, the agreement is deemed in the best interests of the citizens of both units of government;

NOW, THEREFORE, BE IT RESOLVED that the following agreement of understanding be approved.

CITY OF ANN ARBOR–CHARTER TOWNSHIP OF PITTSFIELD POSITION PAPER ON PROMULGATION OF POLICIES

Promulgation of Policies

The CITY OF ANN ARBOR "The City", and the CHARTER TOWNSHIP OF PITTSFIELD, "The Township", by their respective governing bodies, for the purpose of furthering their common welfare, do hereby promulgate certain policies, and declare their intentions to abide the same in their exercise of governmental authority so far as practical and not in conflict with law.

I–ANNEXATION–GENERAL

A. All land areas in The Township lying west of U.S. 23 Expressway and north of the south line of Ellsworth Road from U.S. 23 to the west line of State Road, thence

northerly to the south line of I-94, thence westerly to the western boundary of The Township, shall be designated as "The Territory" and shall be eventually annexed to the City in an orderly manner.

B. It shall be understood that this aforementioned line is the unofficial boundary line until such times it can be so officially designated.

C. Inasmuch as the Township and the City have an existing contract for sewer service for portions of the Township, the Township shall not make plans to provide municipal sewer and/or water service to any properties within said Territory, however the Township shall maintain all other legal authority and responsibility for Township lands and residents in the Territory until such time as they do become annexed to the City.

D. Notwithstanding previous policies, decisions and procedures, the City and Township hereby agree that individual properties in the designated area may be annexed to the City even where such annexation may create new islands. Neither the City nor the Township shall interpose in any judicial or other proceeding pertaining to the annexation of any portion of the said Territory an objection to such annexation by reason that the same would create an enclave of Township land within the City.

E. Neither the City nor the Township shall seek to require annexation to the City of any such enclave of Township land lying within the Territory, solely because of its constituting an enclave, whether now existing or hereafter created through the annexation of a portion of the Territory. Nevertheless, upon request to the City by the owner of a property within any said enclave for City water and/or sewer service to such property, the City may require such property to become annexed to the City as a condition of granting such service.

F. The Township agrees that rather than furthering litigation in the case of the Pittsfield Islands, it will agree to the Boundary Commission decision of 1973 (File No. 8322) if the individual review procedure as set forth in paragraph I-H is applied.

G. Through joint resolutions of the City and Township governing bodies any portion of the Territory within the designated area may be annexed to the City upon the petition therefor signed by the petitioners as provided by MCLA 117.9(8) in the case of such alternate method of annexation.

H. Upon annexation to the City of properties within said Territory the City "deferred charges" thereon, for benefits conferred by capital improvements made prior to the annexation shall be payable at the property owners option, either in full, or in not

less than six (6) equal annual installments, provided that the same shall be payable in up to twelve (12) equal annual installments in cases of a property being, and continuing to be, the homestead of an owner occupant who has special hardship problems or is otherwise adjudged in need of special consideration. Hardship and special considerations may be conferred upon the single owner occupant at time of annexation. A transition appeals committee shall be established for the purpose of determining such need. It shall be authorized to make recommendations to City Council for special consideration and shall be comprised of two (2) members appointed from the City and one (1) member appointed from the Township.

II–MUNICIPAL AIRPORT

A. The City agrees that the pending appeal of the decision of the Washtenaw Circuit Court in the suit of the Township vs. the City (Docket No. 77-12619) respecting the City's proceedings to annex Territories in and about the Municipal Airport and a portion of Eisenhower Boulevard shall be dismissed.

B. The Township agrees to cooperate with the City in the establishment of an Airport Land Use Plan which recognizes the compatibility of light industrial, warehousing, gravel mining and other uses on airport lands. The Township will review and comment on the plan before City adoption. It is further understood that any private construction on Airport lands will require approval under Township zoning and site plan requirements, as well as Township Building and Safety Department permit requirements. Plans for municipal construction on Airport lands must be submitted to the Township for review and comment.

C. The Township agrees to establish a land use plan for the environs of the Airport which recognizes only land uses which are compatible to airport operations from a safety and environmental point of view. The City will review and comment on the plan before adoption by the Township.

D. It is further agreed that gravel mining may take place only for use on City of Ann Arbor roads and public works projects and for use on Pittsfield Township roads, and public works projects. In addition, that a gravel processing plan, a restoration plan and a soil erosion plan be filed and reviewed by the Township.

E. Excepting as exempt by law, the Township shall assess for taxes the real and personal properties of and upon the airport lands.

F. The Township agrees to provide right-of-way for City sanitary sewage mains to the Airport to serve Airport properties uses only.

III–LANDFILL

A. The City desires to expand its Landfill operations to the west on property known as the Derck, Nielsen, and McCalla parcels.

B. The Township agrees to actively support and assist in acquisition negotiations such expansion on the conditions that:

1. A land use and restoration plan be developed for long range use of the landfill area.

2. That a reasonable strip of land immediately east of Stone School Road, as well as along Ellsworth Road, as well as along the northern edge of what is known as the Morgan properties is excluded for environmental purposes.

C. A Landfill Expansion Advisory Committee composed of four (4) persons appointed by the City and three (3) persons appointed by the Township shall be created to advise the City on environmental and operational plans.

D. The Township desires that it be given preferred customer consideration by the City in the use of the Landfill or offered an opportunity for proportionate investment equity if the Landfill is to be expanded in this location.

E. The Township shall not adopt any ordinance, rule or regulation which regulates or attempts to regulate the City's use of the landfill property so long as that property is used for disposal of refuse materials or for park purposes.

IV–SEWER/WATER SERVICEES

A. Upon acceptance and execution of this position paper, the City agrees to immediately approve the Township's request for sewer service limited to the Township Hall and the State Road frontage of a proposed commercial development at Ellsworth and State Roads in accordance with procedures established in Paragraph I-A of the Ann Arbor Pittsfield Sewer Service Agreement dated September 30, 1975. It is understood State Department of Natural Resources approval will be sought eagerly by the City.

B. The sewer service will be provided at 103% of City rates in accordance with the aforementioned agreement.

C. The City will agree to consider additional requests for service prior to the completion of the new "area wide treatment plant" on a case by case basis.

COMMUNICATIONS FROM THE MAYOR

Mayor Louis D. Belcher informed Councilmembers that he will be communicating with Mr. Robert Lillie, Pittsfield Township Supervisor, to advise him of the changes made tonight in the Pittsfield Township Agreement.

* *

Mayor Belcher alerted Council that there are several major Planning matters comming up for consideration, such as the eighty acres of land to be developed in the Briarwood area and a proposal for downtown housing.

* *

Mayor Belcher recommended the appointment of Hugh M. Wanty, 2061 Pauline Boulevard, to the Housing Board of Appeals to replace James J. O'Kane for an indefinite term.

Moved by Councilmember Trowbridge that Council concur in the recommendation of the Mayor.

On roll call the vote was as follows: Yeas, Councilmembers Latta, Greenberg, Morris, Senunas, Sheldon, Trowbridge, Cmejrek, Mayor Belcher, 8

Nays, 0

Councilmember Bell was absent from the Council Chamber at the time the vote was taken.

Chair declared the motion carried.

* *

Mayor Belcher recommended the appointment of Roberta Lea Shrope, 321 South Revena Boulevard, to the Planning Commission, effective July 1, 1978 for a three year term ending June 30, 1981.

Moved by Councilmember Cmejrek that Council concur in the recommendation of the Mayor.

On roll call the vote was as follows: Yeas, Councilmembers Senunas, Sheldon, Trowbridge, Cmejrek, Bell, Mayor Belcher, 6

Nays, Councilmembers Latta, Greenberg, Morris, 3

Chair declared the motion carried.

* *

Mayor Belcher laid the nomination on the table of Charles T. Wagner, 3425 Brentwood Court, to the Planning Commission to be confirmed at the next session of Council.

COMMUNICATIONS FROM COUNCIL COMMITTEES

None.

AGREEMENT SUPPLEMENTING 1979 POLICY STATEMENT RELATIVE TO AIRPORT LAYOUT PLANS, AERONAUTICAL FACILITIES AND NON-AERONAUTICAL FACILITIES AT THE ANN ARBOR AIRPORT

This agreement ("Agreement") is between the City of Ann Arbor ("Ann Arbor"), a Michigan Municipal Corporation and Pittsfield Charter Township ("Pittsfield"), a Michigan Municipal Corporation.

RECITALS:

Ann Arbor owns and operates the Ann Arbor Airport ("Airport"), which is located in Pittsfield Charter Township.

In 1979 Pittsfield and Ann Arbor entered into an agreement entitled "Policy Statement," a portion of which has addressed certain aspects of the operation of the Ann Arbor Airport.

This Agreement is not intended to replace the Policy Statement. However, in the event of any conflict with the Policy Statement, this agreement shall apply.

Under the Michigan Aeronautics Code, MCL 259.1 et seq., Ann Arbor has jurisdictional control for the management, governance and use of the Airport, including application of its police powers, rules, regulations and ordinances, and including the zoning and planning of aeronautical facilities on the Airport property.

The City of Ann Arbor has adopted its construction code, including the building code, electrical code and mechanical code components thereof, in accordance with the Stille-DeRossett-Hale Single State Construction Code Act (MCL 125.1501 et seq.) ("construction code"). The City and the Township do not agree as to the authority granted to the City by the Michigan Aeronautics Code to extend and enforce its construction code at the Airport relative to aeronautical facilities. However, without deciding the extent of the City's authority under the Michigan Aeronautics Code, the City and the Township agree that to the extent it may be necessary, this agreement is an agreement between two public agencies that constitutes an interlocal agreement for purposes of Sections 4 and 5 of the Urban Cooperation Act (MCL 124.504 and 124.505) and Subsection 8b(2) of the Stille-DeRossett-Hale Single State Construction Code Act (MCL 125.1508b(2)) by which the City and the Township agree that the City shall extend and enforce its construction code to all aeronautical facilities constructed on Airport property, including issuing permits, inspections and enforcement of violations.

The Airport is serviced in whole by Pittsfield sanitary sewer service and is serviced in part by Pittsfield water service.

Unless and until Ann Arbor or the Airport qualifies as an authorized public agency for the Airport under Section 9110 of Part 91, Soil Erosion and Sedimentation Control, of

the Natural Resources and Environmental Protection Act, MCL 324.9110, Pittsfield has jurisdiction over the Airport for soil erosion and sedimentation control.

Wherefore, the parties agree as follows:

1. "Aeronautical facilities" means Airport buildings, landing fields and other facilities that are used for and serve aeronautical or aeronautically related operations and purposes. Aeronautical facilities include both facilities constructed by Ann Arbor and facilities that are privately constructed.

2. "Non-aeronautical facilities" means facilities whose use is unrelated to aeronautical operations or purposes.

3. A modification of the Airport Layout Plan is a land use plan as used in Section II.B. of the Policy Statement.

4. If a modification of the Airport Layout Plan is proposed, Ann Arbor will give notice to Pittsfield's Building Official or such other person as Pittsfield designates in writing, of the intent to modify the Airport layout plan at least 30 days before authorizing a professional services agreement for the modification. At least 30 days before submitting a modification of the Airport Layout Plan for approval by the Michigan Aeronautics Commission or the Federal Aviation Administration, Ann Arbor will provide Pittsfield's Building Official with copies of the documents to be submitted to those bodies. After approval of a modified Airport Layout Plan by the Michigan Aeronautics Commission or the Federal Aviation Administration, Ann Arbor will provide Pittsfield's Building Official with a copy of the proposed modification at least 30 days before the Ann Arbor City Council meeting at which it is to be submitted for approval.

5. Annually Ann Arbor will provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with a copy of the five year Airport Improvement Plan for the Airport.

6. If Ann Arbor applies for grant funds for new or expanded facilities shown or listed on the Airport Layout Plan or Airport Improvement Plan it will notify Pittsfield's Building Official, or such other person as Pittsfield designates in writing, of the application.

7. Aeronautical facilities being constructed at the Ann Arbor Airport are not required to go through the Pittsfield site plan review and approval process. However, when civil construction drawings for a project have been completed, but prior to bid for construction of the facilities, Ann Arbor will submit copies of the civil construction drawings to Pittsfield's Building Official, or such other person as Pittsfield designates in writing, for review and comment. The plans submitted to Pittsfield shall consist of four (4) sets of full sized drawings and a description of

the type of project, the general scope and the time frame. All proposed utilities associated with civil construction drawings for a project shall meet all current Township Land Development Standards.

8. Typical administrative fees will not be charged for the review of the plans submitted pursuant to paragraph 7, but the City will be responsible for establishing an Airport Plan (AP) escrow account for costs, which Pittsfield agrees shall be limited to its actual costs for plan review and comment.

9. Pittsfield will provide a written evaluation of the plans specified in paragraph 7 based on the Pittsfield Zoning Ordinance and Land Development Standards to Ann Arbor's Fleet & Facilities Manager, or such other person as Ann Arbor designates in writing, within two (2) weeks of the submittal in order to permit Ann Arbor staff to consider its comments.

10. Ann Arbor will consider and endeavor to incorporate reasonable recommendations provided by Pittsfield.

11. Ann Arbor will obtain soil erosion and sedimentation control permits for the Airport from Pittsfield until such time as Ann Arbor or the Airport qualifies as an authorized public agency for the Airport under Section 9110 of Part 91, Soil Erosion and Sedimentation Control, of the Natural Resources and Environmental Protection Act, MCL 324.9110.

12. Ann Arbor will obtain Pittsfield utility permits as required by Pittsfield ordinance for connections to Pittsfield sanitary sewer or water lines.

13. Ann Arbor shall extend and enforce its construction code, including the building code, electrical code and mechanical code components thereof, to all aeronautical facilities constructed on Airport property and provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with copies of all construction permit documents including the application, the permit, inspection reports and any certificate of occupancy within thirty days of being issued or received.

14. Non-aeronautical facilities at the Airport will be required to comply with Pittsfield planning and zoning requirements and the Pittsfield construction code ordinance.

15. Nothing contained in this agreement shall be construed as limiting Pittsfield's authority to enforce the State Construction Code regarding any violations of that code for non-aeronautical facilities.

16. Nothing contained in this agreement shall exempt aeronautical facilities from being in compliance with the State Construction Code unless said facilities are under the jurisdiction of the Federal Aviation Administration.

17. Ann Arbor shall extend and enforce its fire prevention code to all aeronautical facilities located on Airport property and provide Pittsfield's Building Official, or such other person as Pittsfield designates in writing, with copies of all fire inspection documents including fire alarm and detection systems and fire extinguishing system certification and test reports, and all required operational permits within thirty days of being issued or received.

18. This agreement shall be approved by the concurrent resolutions of the Ann Arbor City Council and Pittsfield Charter Township Board of Trustees.

19. This agreement shall take effect October 1, 2009 or after a copy has been filed with both the Washtenaw County Clerk and the Michigan Secretary of State, whichever is later.

20. This agreement shall have a term of 5 years beginning on October 1, 2009. It shall automatically renew for successive 5 year periods unless either party provides the other with written notice of non-renewal at least 60 days before the end of a term.

Ann Arbor Municipal Airport (ARB), Ann Arbor Michigan - Draft Environmental Assessment FAA Combined Comment Matrix

--May thru October 2016--

Comment Number	Page Number	Section Number	Paragraph	FAA Comment	MDOT Comment Resolution
1	1	title page	n/a	Need statement that "This Environmental Assessment becomes a *Federal* document…" before the FAA signature block, per FAA Order 1050.1F paragraph 6-2.1(a).	Revised draft EA
2	1	title page	n/a	Federal signature block should read "Responsible FAA Official"	Revised draft EA
3	9, 10 & 12	1.3 & 1.4	all	The Intro and background sections are discussing the State Standards. What are the Federal Requirements, in addition to the State reqmts? Critical Aircraft (1.5.1) & use of runway, Aircraft Activity (1.5.2) and Characteristics /Recommendations (1.5.3) all need to be in the background section before purpose and need section. Info in P & N needs to be in the background section.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The draft EA was revised to try and clarify the issue raised here, yet remain consistent with the example previously provided.
4	10	1.3	6	Need a discussion of the SBGP so that the reader is better able to understand the division of porposed actions between state and Federal	Revised draft EA
5	10	1.3	6	The paragraph is implying that the ALP is "fully approved".. If this were the case, it would have been unconditionally approved rather than conditionally approved. - Remove, "…it is in fact a fully approved ALP" - Add "conditional" to the last sentence, "...prior to AERO signing the conditional approval letter."	Revised draft EA
6	12	1.3	2	Please explain why the comments from the ADO were not addressed.	Revised draft EA
7	12	1.4	3	Is the purpose to meet the "FAA design objectives" or to accommodate the runway length needed by critical aircraft? This is implying that FAA is forcing the runway extension. Recommend changing the wording to clarify that aircraft are currently impacted by the shorter runway length. Is "increasing the line of sight for ATCT personnel" (presumably to improve a hotspot) more of a Need than a purpose?	Revised draft EA

8	12	1.4	4	States that the Need is to allow aircraft to operate at "Optimum Capabilities", should this include why there's a need to operate at "optimum capabilities"? Where are aircraft going, how often is the runway length affecting users?	In response to FAA's question regarding the need to allow the majority of critical aircraft to safely operate at their optimum capabilities without weight restrictions, we reference Paragraph 103 of FAA Advisory Circular 150/5325-4B, *Runway Length Requirements for Airport Design* . This paragraph states "The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions". The term "regularly use it" is further identified by the FAA as being the volume of usage provided by the runway's particular critical aircraft category (a minimum of 500 Annual Itinerant Operations). As far as FAA questions related to where the aircraft are going, an Origin-Destination Analysis was conducted using records obtained from the FlightAware Instrument Flight Rules (IFR) flight plan database associated with ARB. Flight operations were verified between ARB and at least 31 other states (approximately 63% of the continental U.S.). A list of all of the states involved is included in User Survey Supplemental Report No. 2, which is included in Appendix A-2 of the Draft EA. Additional information related to both of the above paragraphs is included in Sections 1.5.1, 1.5.2, and 1.5.3 of the Draft EA. Revised draft EA where appropriate.
9	12	1.4	3	Another sentence should be added after the first sentence of the paragraph to explain that the Purpose includes lengthening and shifting the runway. The second sentence is a Need and should be placed in the following paragraph.	Revised draft EA
10	12	1.4	all	Use of the term "Safely" implies the airport is not safe currently.	Revised draft EA
11	12	1.4	all	The purpose and needs statement should be complete and concise. This would include stating the problem that is looking to be addressed. A statement of overall safe and efficient and usable is a general statement and should be tightened up to reflect the discussion that follows. It is confusing on why the line of sight issue is singled out in the statement. Consider revising this statement.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The draft EA was revised to try and clarify the issue raised here, yet remain consistent with the example previously provided.
12	12	1.4	4	Clarify why the statement regarding aircraft says majority and not "all' aircraft?	Revised draft EA

13	13	1.5.1	2	Clarify whether the critical aircraft is properly grouped; is it okay to use the category B-II Small Aircraft? Cross reference B-II Large in the document.	The critical aircraft category of "B-II Small Aircraft" is properly grouped. In conducting the analysis of the critical aircraft, the distinction between Small versus Large category aircraft was considered in order to determine which Runway Length Curves in FAA Advisory Circular 150/5325-4B would be applicable to ARB. The curves in Chapter 2 are applicable to Small category aircraft, and the curves in Chapter 3 are applicable to Large category aircraft. The FAA recommended runway length of 4,200' was obtained from Figure 2-2 of Chapter 2. Had the critical aircraft at ARB been determined to be of the Large category, Tables 3-1 and 3-2 of Chapter 3 show that a much longer runway length would have been recommended by the FAA Advisory Circular. As far as FAA's request to cross reference the B-II Large category in the EA document, it is clearly referenced in section 1.5.3.
14	13	1.5.1	5	This paragraph is general in nature. A runway of 4,300 feet would allow without load restrictions… why 4,300's, why not 4,500, 5,000, or 10,000. The paragraph should instead define the runway length needs of the aircraft regularly using the runway, including haul lengths and loads rather than suddenly put out that 4,300 ft. would satisfy it.	As explained in Section 1.5.3, The FAA recommended runway length of 4,200 feet at ARB was obtained by calculation following the methodology referenced in Chapter 2 of FAA Advisory Circular 150/5325-4B, "Runway Length Requirements for Airport Design," a publication that is used nationally by the agency. The methodology and figures referenced in this section of the AC result in recommended runway lengths that are airport-specific, and they can vary by hundreds of feet from site to site, depending on the specific airport elevations and mean daily maximum temperatures used in the calculations. For example, if a representative higher-elevation airport in the Denver area had an elevation of 5,000 feet MSL, interpolation of Figure 2-2 of Chapter 2 of the AC shows that a runway length of approximately 5,000 feet in length would be recommended for the same B-II Small category of critical aircraft. In Michigan, airport elevations at our public-use airports only range from 578 feet to 1,622 feet MSL. The AERO runway length recommendation of 4,300 feet is a statewide standard for all airports in the state with category B-II critical aircraft classifications, as identified in Table 40 of the Michigan Airport System Plan (MASP). Since airport elevations and mean maximum temperatures do not vary significantly from airport to airport in Michigan, as opposed to many other states, AERO uses a single runway length recommendation for all airports of the same critical aircraft classification.
14 Cont.	13	1.5.1	5		The reason that the preferred alternative in the draft EA references a runway length of 4,300 feet is that this length meets both FAA and AERO runway length recommendations for critical aircraft in the B-II Small category.

15	13	1.5.1	6	The example seems to be an extreme case, how often does this user use the airport and what type of B-II aircraft is it? Why do they base at ARB instead of another close airport if they cannot use the aircraft to it's max capability above 40 degree F?	This user flies approximately 200 operations from ARB annually in Cessna 560 Excel jet. The user's business is based in Ann Arbor and the proximity to the airport provides convenience and a significant time savings over other local airports.
16	14	1.5.1	1	"Part 135 operators must reduce the useable length of the runway by anywhere from 20-35% based on runway conditions" has this quote been verified through citation to the actual Part 135?	The corporate pilot quotation regarding Part 135 operators has been verified to 14 CFR 135.385 paragraphs (b) and (f).
17	14	1.5.2	2	"Also, approximately 67% of the IFR flight plan records examined were between ARB and out-of-state locations." It's not clear how far of a distance these itinerant operations are going.. Are they all to surrounding States or are the haul length further?	The first sentence of Section 1.5.2 of the draft EA refers the reader to User Survey Supplemental Report No. 2 in Appendix A-2 for full details regarding the Origin-Destination Analysis. Exhibit No. 2 in the User Survey Supplemental Report lists the names of all 31 states (and Washington DC) that were associated with flights to and from ARB, as obtained from just the IFR Flight Plan database of FlightAware. Potentially, there are even more states associated with ARB flights than those confirmed by the referenced FlightAware records. Nonetheless, the records reviewed confirm that direct flights were conducted from ARB to other airports located in states as far away as Arizona, Texas, Florida, and Maine, just to name a few. The confirmation of flight operations between ARB and at least 31 other states verifies that operations are not confined to the few states surrounding Michigan, and that flights with long distance stage lengths are being conducted.
18	14	1.5.2	2	Second half of paragraph: Why are NetJets and AvFuel further called out in the two final sentences? What about the other six companies?	While many of the large corporations listed as users of ARB are commonly known, NetJets and AvFuel were lesser known entities that are active at the airport. NetJets because of the variety of businesses they serve and AvFuel because they are a local business.
19	16	1.5.3	FAA	Clarify why 4,200' (AC 150/5325-4B) would not support the Purpose and Need (P& N) as opposed to the requested 4,300.'	As explained in section 1.5.3 of the draft EA, utilization of current FAA runway design standards results in a recommended runway length of 4,200 feet at ARB. Utilization of current AERO runway design standards results in a recommended runway length of 4,300 feet. Although the recommendations are very similar, the reason that 4,300 feet was referenced in the draft EA in meeting the purpose and need is that it meets both the FAA and AERO current standards for runway length recommendations based on the critical aircraft category of aircraft.
20	16	1.5.3	FAA	Why isn't 4,200' listed as an alternative?	As explained in Comment 19 shown above, the reason that a runway length of 4,200 feet was not included as an alternative is that it is very similar in length to the 4,300 foot long alternative, and it does not meet current AERO runway design standards.
21	16	1.5.3	3	"The AERO recommendation of 4,300 feet is a statewide standard…" Recommend including how AERO developed their standard. What is this length based on, is it a random length they chose or does it meet the requirements identified in the P&N (optimum capabilities of the critical aircraft at ARB)?	Revised draft EA

22	16	1.5.3	4	Clarify whether the category B-II Small Aircraft requires a runway length of up to 4,300, or do the larger B-II airplanes require this length? The Small B-II may be on the lower end of the spectrum?	Revised draft EA
23	16/17	1.5.4	8 (last)/several	Clarify why User-Survey Reports were heavily relied upon? Why not TAF and Tower Counts? TAF was very close to accurate, however it is not logical to conclude (quantitative to qualitative) that ops will increase, because TAF may not always support constant increase. (Justify, e.g. is there a new coach that may boost attendance for Michigan games which will increase probability of increased attendance/travel?)	The reason that User Survey Reports were relied upon in this study is that they distinguish between the various aircraft makes and models, while the TAF and Tower Counts do not. From the various make and model information, aircraft approach categories, design groups, weight classifications (large vs. small), and critical aircraft categories can be determined. The TAF shows total numbers of forecasted operations, but no distinction of aircraft makes or models. The Tower Counts show historical numbers of total operations, but no distinction of aircraft makes or models. All three data sources (user surveys, TAF reports, and Tower Count reports) are useful for different aspects of analysis and forecasting, and all of these sources were used appropriately in this study. As stated in paragraph 1.5.4, the current TAF (which is prepared by FAA personnel and updated annually) forecasts continually increasing operations at ARB from year 2014 through year 2040, and the current MASP (which is prepared by MDOT personnel and updated periodically) also forecasts similar numbers of continually increasing operations through year 2030.
24	17	1.5.4	4	The paragraph indicates that the TAF is used to project forecasted operations to 2040. Does the airport have a locally developed forecast to compare this to? Does the airport understand how the TAF was developed and if it's really a good indicator of B-II itinerant ops?	While the airport does not have a locally developed forecast, the current FAA-developed TAF as well as the current MDOT-developed MASP both show continually increasing operations at ARB from present date at least through the year 2030. It is logical to conclude that all categories of aircraft that use the airport would show some increase in their annual operational numbers as part of the overall increase in activity. But even if category B-II operations remained at the level of the 538 annual operations that were documented in year 2014, and the entire increase in operations was attributed solely to increased activity by the smaller categories of aircraft (highly unlikely – especially if the runway is extended to 4,300 feet in length as proposed), the justification for the proposed project would still be substantiated both presently and through future years.
25	17	1.5.4	5	"…it is logical to conclude that operations by B-II category aircraft and larger will also increase beyond the 551 that were documented in 2014." Table 1-1 indicates that the 5-year trend from 2010 to 2014 is a steady or downward trend in B-II ops. Why is it logical to believe B-II ops will increase given the history of ops at the airport? - does the 551 include just B-II aircraft or B-II and larger as indicated in the paragraph? - How many of the 551 ops by B-II aircraft are by the representative King Air 200 or aircraft with 10 or more passenger seats?	Changes made and clarification added to Section 1.5.4 as requested. A table has also been added to User Survey Report No. 4 (Exhibit 1 of Appendix A-4 of the draft EA) which clarifies the number of annual operations conducted in 2014 by specific aircraft models and groupings (B-II, B-III, and C-III). As a result of preparing the table and analyzing and categorizing the operations by specific aircraft models, the operations performed exclusively by category B-II aircraft have been revised to 538 instead of the 551 that were mentioned in the previous draft of the EA. A total of 544 annual operations were performed by the combined B-II and Larger categories of aircraft. The text in Section 1.5.4 as well as numbers shown in Table 1-1 have been revised accordingly.

25 Cont.	17	1.5.4	5		In answer to FAA's question regarding a "steady or downward trend in B-II ops" from year 2010 to 2014: Table 1-1 of the draft EA does show minor fluctuations in the levels of estimated annual B-II operations during this time frame, from a low of 537 to a high of 600. These numbers were based on the minor fluctuations in total operations that occurred during the same time frame. The trend is not a steady downward trend as FAA suggests, but rather the numbers fluctuate both downwards and upwards. The numbers are also relatively close to each other, as opposed to being drastically different. The severe and multi-year economic recession that originated in 2009 likely played a role in the minor fluctuations of the total operations at ARB during the time frame in question, and as a result the minor fluctuations in the number of estimated B-II operations. Since the TAF (which is prepared by FAA personnel) shows that Total Annual Operations at ARB are forecasted to increase every year beyond year 2014, it is logical to conclude that operations by B-II category aircraft will also increase beyond the 538 that were documented in 2014. As noted in the text of revised Section 1.5.4 of the draft EA, even if B-II category operations do not increase in the future, but remain the same as in year 2014 (very unlikely if total operations are increasing), justification for the proposed runway extension would still be substantiated through the year 2040.
25 Cont.	17	1.5.4	5		In answer to FAA's questions regarding more details of operations performed by "B-II" versus "B-II and Larger" categories of aircraft, as well as more specifics regarding individual aircraft types, the information is shown in Exhibit 1 of User Survey Report No. 4 (see Appendix A-4 of the draft EA).
26	17	1.5.4	6	"These numbers have been calculated based on the percentage of actual B-II operations to actual Total Operations…" Why wasn't flight aware and FAA data used to determine actual usage by B-II aircraft over more years? Was FAA or Flight Aware data compared to the Airport User Survey data used for 2007, 2009, and 2014?	Changes made and clarification added to Section 1.5.4 as requested. In answer to FAA's questions, FlightAware data was used in the determination of B-II operations for survey data years 2007 and 2009, and FAA's Traffic Flow Management System Counts (TFMSC) data was used in the determination of B-II operations for survey data year 2014. This is clearly explained in User Survey Report Nos. 2, 3, and 4 (see Appendices A-2, A-3, and A-4 of the draft EA). Also, Exhibit 1 in each of these three reports shows a listing of the specific B-II category aircraft that were included in these records. Operational data obtained from both the FlightAware and the TFMSC sources is considered the most accurate available, as it is based on actual documented operations obtained from Flight Plans filed by pilots, over an entire calendar year of time. None of the data is based on estimates of annual operations generated by pilots, or proration of partial year survey data, as is common in conducting many other operational surveys.
27	20	1.6	first	First sentence should read: "The City of Ann Arbor proposes to extend and shift 160' the existing…"	Revised draft EA

28	20	1.6	2	"…as it does not currently meet the FAA design objectives" Recommend that all references to "FAA design objectives" be removed… the purpose should not be to meet FAA design objectives or put the onus on the FAA causing the runway length, but their user need for the longer runway	Excerpt directly from Purpose and Need...The **Purpose** of the proposed actions is to provide facilities at ARB that fully accommodate the operational requirements of critical aircraft currently using the airport, while at the same time enhancing safety. Revised draft EA as appropriate.
29	20	1.6	3	First sentence should read: "The existing runway approach light system pilots use to identify…"	Revised draft EA
30	20	1.6	3	After the second sentence, the remainder of the paragraph should read: "Due to difficulty in maintaing the system, the ODALS are currently temporarily out of service. Due to the fact that the Runway 24 end is proposed to be relocated, the FAA is proposing to permanenty decommission and remove the ODALS according to an FAA airspace letter signed on May 13, 2015, Airspace Case Number 15-AGL-14NR (Appendix H). A new runway approach lighting system will not be constructed as part of the proposed action."	Revised draft EA
31	20	1.6	4	Clarify throughout the document the direction of rw/taxi shifting and extension - either west or southwest	Revised draft EA where appropriate.
32	20	1.6	4	The Shift and Extension of the existing runway should be clarified, is the physical pavement going to be shifted and extended or is the pavement just going to be extended and the Runway 24 threshold moved 150 ft. If the remaining 150 ft pavement remains, is it usable? How will the existing taxiway across the threshold be handled (to the southeast)?	Revised draft EA to clarify, details contained in "proposed action" bulleted list.
33	20	1.6	5	delete entire paragraph, as this is not the appropriate section for this discussion.	Revised draft EA
34	20	1.6	6	Paragraph should read: "Implementation of the Preferred Alternative would meet the Purpose and Need by adequately addressing the needs of the…"	Revised draft EA
35	21	1.6	first bullet	To clarify the meaning, please reword this bullet	Revised draft EA
36	21	1.6	second bullet	specify that the parallel taxiway is designated Alpha	Revised draft EA
37	21	1.6	bullets 1, 2, 3	Clarify that 150' is being removed from the northeast end of the runway and added to the southwest end. Runway is being extended by 795'; please label the taxiway and rw; delineate why it is being extended by 945' if the new runway portion will be 795' once the 150' is newly constructed.	Revised draft EA (addressed by Comment #35)
38	21	1.6	bullets 1, 2, 3 & 4	Clarify whether entire runway is being reconstructed, or just portions to determine impacts.	There are no proposed actions to reconstruct the entire runway and the draft EA is clear that the proposed actions only impact the proposed 795' extension and the proposed 150' shift.
39	21	1.6	bullet 5	Reiterate throughout the document direction of the shift/extension	Revised draft EA where appropriate.
40	21	1.6	seventh bullet	Should read: "Relocate airport-owned Precision Approach…"	Revised draft EA
41	21	1.6	tenth bullet	Should read: "Relocate/reconstruct FAA-owned Ruwnay 6 Runway End Identifier…"	Revised draft EA
42	22	1.7.1	after first bullet	add new second bullet: "FAA acceptance of relocated NAVAIDs (REIL)	Revised draft EA

43	22	1.7.1	third bullet	I was unaware that this project would use AIP funds. If this is not the case, reword with the correct funding source or delete	In a December 2013 email between the FAA-Region and MDOT-AERO, the funding sources intended for the project were clarified and remain the same, State Apportionment, Non-primary Entitlements and State/Local Shares will be used.
44	22	1.7.1	3	This bullet needs to be removed. There are no AIP funds being sought or provided for this proposed action.	State Apportionment and Non-primary Entitlements are AIP funds.
45	22	1.8	all	The section labeled, "Other considerations" should be included in the purpose and needs section. These issues kept separate from the statement objectives makes it difficult to have a clear purpose and need statement and to recognize these as part of the project.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The draft EA was revised to try and clarify the issue raised here, yet remain consistent with the example previously provided.
46	22	1.8.1	1	"The proposed shift would enahance operatinal safety, and possibly prevent a runway incursion, by expanding the view of the hold area and paralle taxiway to ATCT personnel." Therefore, please clarify, does this this shift cause other operational issues with the existing Northeasternmost hangar apron view still blocked from ATCT line of sight? How will aircraft taxi to the Southeast hangar section? - Is 150 ft enough of a shift to remove the hot spot?	With the proposed shift of the A1 connector from Alpha Taxiway to Runway 06/24 to the southwest, the Line of Sight issue will be significantly improved. Aircraft entering the Movement Area from Echo, Delta and Charlie (east facing hangars only) will still have limited visual oversight by controllers. This will be a significant improvement over current conditions where all aircraft using the taxiway hold area of Runway 24 are in a restricted visibility area. The existing Delta taxiway from the southeast hangars will be shifted to the southwest as well under the proposed project. This will allow them full access from Runway 06/24 to the southeast hangar area with full visual access from the control tower. The proposed 150' shift will significantly improve the safety of ground operations of taxiing aircraft. While some visual restrictions for aircraft originating from the northeastern most T hangars will remain, it will be up the FAA to determine if this area should still be designated as a "hot spot."
47	23	1.8.1	second on page	In response to the first sentence, clarify what type of "more negative impacts" would there be?	Revised draft EA
48	23	1.8.1	2	"…than with the runway theshold shift alternative"… is the preferred alternative to shift the threshold only and leave the pavement, or to shift and remove the 150 ft of pavement?	Revised draft EA to clarify, details contained in "proposed action" bulleted list. (Section 1.6)
49	23	1.8.1	3	"…raising the tower in its existing location would very likely result in the tower penetrating the 7:1 transitional surfaces…" Has an airspace study been completed to determine if this is a hazard?	Changes made and clarification added to Section 1.8.1. In answer to FAA's question, yes an airspace study was completed to determine if a raised tower would become a hazard. See revised Section 1.8.1 for details.
50	23	1.8.1	4	How old is the ATCT? Is it due for a modernization or rehab that might cause it to be beneficial to move it?	The ATCT was constructed in the mid-1970's and the attached office structure was constructed around 2003. The ATCT exterior was rehabbed within the last 5 years. The Airport is unaware of any pending plans for additional modernization or rehab.
51	23	1.8.1	4	Delete "disruption of Airport Traffic Control operations"	Revised draft EA
52	23	1.8.2	1	"The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach slope…" Why are they protecting for a 34:1 approach slope when the minimums for existing approaches are 1 mile? 34:1 is typically required for minimums below 3/4 mile. If the 34:1 doesn't apply, why would this be a "concern"?	The 34:1 approach slope is planned for future developments at ARB on the current ALP. (Sheet 4 - "Airport Layout Plan (Future)") Plus, any lowering of obstacles in the approach to a runway is an improvement and should always be attempted to improve the safety of the flying public.

53	23	1.8.2	5	Justify the slope gradient based on page 2 of the AC 150/5325 (10) Effective Runway Gradient	The justification of the slope gradient based on page 2 of the AC 150/5325 (10) Effective Runway Gradient will be accomplished once detailed design is performed on the preferred alternative.
54	24	1.8.3	1	Regarding 150/5235 4-B, Figures AC 2-1 and 2-2, an engineer from ARPs stated that the charts support the runway being extended to 4,150 when the temperature is higher than 82.5◦. But if the sponsor believes the longer runway is necessary please justify.	The mean daily maximum temperature of the hottest month of the year at ARB is 83.0 degrees F (July). The airport elevation is 839' MSL. When these numbers are factored into Figure 2-2 of FAA AC 150/5325-4B, the resulting recommended runway length is 4,200'. See the draft EA for additional information regarding the FAA recommendation of 4,200' versus the MDOT recommendation of 4,300'. (Section 1.5.3)
55	24	1.8.3	3	Please explain what is meant by a "local objective"	A "local objective" is a goal set by Ann Arbor Municipal Airport leadership that would be obtained by the implementation of the proposed airfield improvements.
56	24	1.8.3	3	several comments. How many overruns occurred? This objective should not be labeled as a local. The runway design criteria accounts for RSAs an RPZ for the critical aircraft.	Eleven overruns have been documented. If additional overruns occurred, the Airport has been unable to find verifiable documentation for them. As overruns are not officially recognized by the FAA or AERO as justification for extending a runway, the objective of keeping aircraft on the pavement is a local one. While the existing RSA and RPZ meet the design criteria for critical aircraft, the Airport believes that keeping aircraft on pavement instead of transitioning to an RSA or RPZ reduces the hazard to aircraft, their occupants and the airport facilities.
57	24	1.8.4	1	This section is being viewed as part of the justification for the statement. Commerce can not be of the P/N. Otherwise, other commerce alternatives will have to be included. Suggest that this section be removed.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The items included as "Other Considerations" are not items to justify the proposed project but are other items that will be impacted if the proposed project is constructed. These items are of significant interest or impact that they warrant explanation.
58	25	1.9	third bullet	How would the project "enhance operational safety in low-visibility conditions" without installing an ILS? Would providing a 34:1 approach really be enough to make this claim?	In answer to FAA's question, the project would enhance operational safety in low visibility conditions by providing a greater margin of safety between the approaching aircraft and the obstacles on the ground in the Runway 24 approach area. Since the 34:1 approach surface provided by the proposed project is flatter than the existing 20:1 approach surface, obstacles with heights just below the 34:1 surface would be farther away (vertically) from overflying aircraft than obstacles with heights just below the 20:1 surface. The greater vertical distance of object-free airspace would obviously increase the margin of safety in low visibility conditions.
59	25	1.9	last bullet	explain "local objective"	(Addressed by Comment #55)
60	25	1.9	all	The summary should be moved up and be made part of the P/N statement and renamed objectives. The document to this point uses safely through out. Either remove the language or change to enhanced safety.	MDOT-Aero and the FAA-Region have had previous discussion regarding the summary, the summary will be left in place. Revised draft EA to address safely/enhanced safety where appropriate.

61	26	2	1	include the number of alternatives at the beginning of the sentence. Drop the rest of the sentence after "project"	Revised draft EA
62	26	2.1.1	3	In regards to the second and third sentences of the paragraph: Does the fact that B-II aircraft still land at ARB instead of nearby YIP demonstrate that the restrictions put on those aircraft by the short runway are not significant, otherwise these users would land at YIP instead? For clarity, this should be rebutted in order to strengthen the Purpose and Need	The Ann Arbor Municipal Airport cannot dictate which airfield a pilot uses. Many factors go into that aircraft operator's decision on where to operate from. B-II aircraft are a regular user of the Airport and the existing runway configuration does not satisfy the FAA design objective of providing sufficient runway length to allow airplanes that regularly use it to operate without weight restrictions. The proposed project would also result in ARB achieving full compliance with all AERO basic development standards outlined in the MASP 2008 for category B-II airports.
63	26-28	2.1	all	What were the criteria used to dismiss these alternatives. For example, there is no mention of environmental impacts etc. in the purpose and needs statement	As is consistent with the standard EA process, alternatives are most commonly dismissed because they failed to meet the Purpose and Need or other alternatives had less harmful impacts on the environment.
64	28	2.2	1	how were these alternatives deemed feasible?	As is consistent with the standard EA process, alternatives are typically only carried forward if they meet the Purpose and Need and avoid, minimize, and/or appropriately mitigate impacts on the environment.
65	29	2.2	3	Build Alt 3 - label the parallel taxiway that will be extended; will a portion of the taxiway or all be demolished and reconstructed? Or new construction to southwest?	Existing taxiway connector Alpha1 will be demolished on the northeast end of the runway and reconstructed 150' to the southwest. The parallel taxiway will be extended with new construction to the southwest. Revised draft EA.
66	33	Figure 3.4	map	For clarity please label the taxiway and runway and the lengths, on the same map	Revised draft EA
67	34	2.3.1	2	The airport is currently safe. This section implies the airport is unsafe.	Revised draft EA
68	35	2.3.3	1	Line of sight is not listed as an objective. Need to make sure the P/N statement is concise, clearly stated, focus, with justification and objectives. Please provide better clarity/flow when tracking the P/N section.	Line of Sight is shown as a "Need" in the revised Purpose & Need section and is consistently addressed in each of the alternative evaluations.
69	35	2.4	1	Clarify that the preferred ALT 3 is to remove 150' from the east end of the runway, (adding back 150' on the west end) plus the adding the 795' and shifting to the southwest	Revised draft EA
70	35	2.4	2	Add on to end of first sentence: "except for the ODALS."	Revised draft EA
71	35	2.4	2	Third sentence should read: "FAA approval for the relocation of the REILS will be required as part of the proposed action."	Revised draft EA
72	35	2.4	2	Fifth sentence should read: "If the decommissioning proposal is finalized, the approach lighting system will be removed and no relocation will occur."	Revised draft EA

73	36-68	3	all	This section needs to use the environmental impact categories specified in FAA Order 1050.1F, paragraph 4-1	The draft EA has been in process continually since 2009 and significant effort has gone into preparing it in accordance with FAA Orders 1050.1E and 5050.4B. Also, as previously mentioned in this comment matrix the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft, it was also prepared in accordance with 1050.1E. Because this change would result in no change to content and the regulatory agencies, tribes and public have previously reviewed the draft EA as is, MDOT-AERO proposes to leave the draft EA unchanged.
74	36	3.1	1	What about the other noise impacts, such as from construction activities?	Noise associated with construction activities is covered in Construction Impacts category not the Noise category. (Section 3.15) Revised draft EA to clarify.
75	36	3.1	all	What about evaluation of the no action alternative for noise impacts?	Included in Section 3.1.2
76	36	3.1.1	1	The title of the methodologies need to be included in the paragraph	They are described in the same section.
77	37	3.1.1	last four bullets on page	Update these sources with more recent versions	These are the original sources used for the 2009 Noise Impact Analysis and should remain for consistency. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
78	39	3.1.3	all	Why not just redo the noise analysis with 2015 data?	The effort, timing and cost associated with redoing the noise analysis does not seem prudent, especially for little anticipated change in fleet mix and night operations, and a forecasted decrease in annual operations from the level analyzed in the original 2009 noise analysis. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
79	41	4.1	map	Noise Contour - Existing Conditions, please clarify the year.	Revised draft EA
80	42	4.2	map	No build - are the existing conditions still the same? Reasonable representation?	Revised draft EA. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
81	43	4.3	map	Preferred Alternative - Please delineate the projection out for the next five years	Revised draft EA. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
82	46	Figure 4.4		Is a newer source available than June 2011?	No
83	49	Figure 4.7		Is a newer source available than June 2011?	No
84	50	3.3.2	4	Update U.S. Census data with more recent source	Revised draft EA
85	51	3.3.2	1	Update U.S. Census data with more recent source	Revised draft EA
86	51	3.3.2	2	Update U.S. Census data with more recent source	Revised draft EA
87	52	3.3.4	4	Update U.S. Census data with more recent source	Revised draft EA
88	53	Table 3-2		Update U.S. Census data with more recent source	Revised draft EA

89	55	3.4	1	According to the Federal Register EPA 40 CFR Part 81 which was published in January of 2015, using the latest information from 2012 Annual Fine Particulate Matter NAAQS, Washtenaw (Livingston, Macomb etc.) County; PM 2.5 is Unclassified attainment. Clarify that the data submitted is correct.	The following is an excerpt directly from the 2014 Michigan Annual Air Quality Report published in June 2015 - All Michigan counties from 2010-2014 met the 1997 annual PM2.5 standard of 15 μg/m3 and the 2006 24-hour PM2.5 standard of 35 μg/m3. The EPA designated Michigan in attainment of these standards in August 2013. In December 2012, the EPA revised the annual primary standard to12 μg/m3 while the annual secondary standard remained at 15 μg/m3. The primary and secondary 24-hour standard remained as 35 μg/m3. The EPA has not made designations for the 2012 NAAQS revisions; however, PM2.5 concentrations are below 12 μg/m3 throughout Michigan. (DEQ 2016 Attainment Map Appendix C)
90	55	3.4	3	In regard to air quality, please provide the data from MDEQ (Do not see in Appendix D - there is a Land and Water Management and Wetlands letter)	Appendix D is specifically for "Early Agency Coordination" documentation, Appendix H is for "Additional Agency Correspondence" and includes the letter from MDEQ to EPA.
91	55	3.4	4 thru 7	The discussion does not quite fit affected environment. In terms of air quality what is the baseline conditions.	This language was not included in the first draft EA, however during discussions with the FAA-Region during review of this draft EA, this language was specifically recommended and later provided by the FAA-Region for inclusion into this draft.
92	56	3.4	3	Is there are more recent study than the L&B study from 1996?	No
93	56	3.4	3	Fourth sentence: which standards is this referring to?	NAAQS as referenced in the following sentence.
94	56	3.4	3	Last sentence: The reference to "proposed projects at general aviation airports" is very broad. How could the report know the extent of future projects at all GA airports in MI, especially if the report in 20 years old?	It is assumed that the report considered past GA airport projects and their typical scope and impacts when referencing proposed projects and made the general assertion that those projects are typically not of the scale to contribute to any NAAQS exceedances.
95	56	3.4	4	Please reword paragraph, as it is very confusing	Revised draft EA
96	56	3.4	4	It is not clear if this area is in a nonattainment area or maintenance area. Also not how this estimate was achieved. What calculations, models and sources were used. The citing of the court case should be removed and CAA regulations should be cited.	Based on the 2014 Annual Air Quality Report all of Michigan is in attainment. The following is an excerpt directly from the 2014 Michigan Annual Air Quality Report published in June 2015 - "Michigan ambient NO2 levels have always been well below the NAAQS. Since March 3, 1978, all areas in Michigan have been in attainment for the annual NO2 NAAQS...all monitoring sites have had an annual NO2 concentration at less than half of the 0.053 ppm NAAQS. As such, the DEQ requested a designation of unclassifiable/attainment for the entire state. Unclassifiable/attainment means that there are no air quality measurements that would justify classifying these attainment areas as either serious or moderate nonattainment areas." (DEQ 2016 Attainment Map Appendix C)
97	56	3.4	5	First sentence referenres NOX - what about the other NAAQS?	Revised draft EA.
98	56	3.4	5	Last sentence: replace "should" with "would"	Revised draft EA
99	57	3.5	1	How was it determined that the water quality is degraded. Was MDEQ contacted? With out some reliable way of establishing this the baseline for environmental conditions is not met.	There was no formal determination that it is degraded, only as it states, that it is "likely degraded", based on the existing conditions, observations and characteristics provided. Given that this is primarily a storm water dominated system, as described, it doesn't seem unreasonable to conclude that it is likely degraded, as it is common thought that many storm water dominated systems are.

100	57	3.5.1	4	Please clarify the status of the NPDES permit, as mentioned in secton 4.2.2? The reason for the permit should also be stated.	There are two distinctly different NPDES Storm Water Discharge Permits at ARB, one permanent for municipal storm water discharges and the other temporary for storm water discharges associated with construction activity. Revised draft EA to clarify.
101	57	3.5.2	2	Did not find a map that shows the 14 soil units and how their location to the proposed action site	Revised draft EA
102	58	3.5.2	1	Did not find a map that shows the wellhead area in relationship to the proposed action site.	A map of the City of Ann Arbor's Wellhead Protection Areas is now included. (Appendix H) The airport is located within the Steere Farm Wellhead Protection Area.
103	58	3.5.2	4	What about soils? The paragraph also mentions a new water line. Please provide more info on the water line.	The City replaced an existing raw (untreated) water line with a new 30" raw water line in 2010 along the east side of the airport. (Appendix H)
104	61	3.7	1	What were the results of the survey?	Revised draft EA
105	61	3.7	3	Did SHPO/THPO provide concurrence? If so, please state so.	Yes. Revised draft EA
106	61	3.8	2	Fourth sentence: be more location-specific, as the way the sentence is worded makes it sound the grassy meadows are within the RSA.	Revised draft EA
107	61	3.8	2	Last sentence: This discussion should be expanded. What does the agreement call for? Why does it exist?	This discussion is already included in Section 3.9 Threatened & Endangered Species and Section 4.2 Mitigation Measures.
108	62	3.8	4	Third sentence: What does the Audubon society think of this? Were they contacted as part of the EA public outreach process?	Revised draft EA
109	63	3.9	1	Update June 2009 survey, as this is already seven years old.	Revised draft EA
110	63	3.9	3	Last sentence: Did Audubon agree with this as well?	Revised draft EA
111	63	3.9	3	Update letters from 2009 for preferred alternative (Department of Natural Resources have instructions that may have changed)	As soon as this draft EA is finalized, the regulatory agencies will be contacted in writing and given the opportunity to review, comment and/or update their instructions.
112	63	3.1O	1	Update June 2009 survey. As part of the wetlands analysis, was USACE contacted? If so, did they make a jurisdictional determination? Are there any wetlands on the Rwy 06 approach, as the USFWS map depicts a wetland area. What about the removal of the ODALS - will this action impact the wetlands?	Review of available data sources was completed in 2015 and appear largely consistent with what was found in 2009. MDOT-AERO will complete a real-time field review of project areas to confirm the presence of wetlands, or lack thereof, during project design to ensure proper permitting requirements are met, if necessary. In Michigan, the USACE only retains authority over certain wetlands, the USEPA has agreed that MDEQ has compliance responsibilities over all the rest. Both MDOT-AERO and MDEQ have concluded that the wetlands at ARB are not regulated by USACE.
113	64	3.11	3 and 4	Was the floodplain analysis and conclusion confirmed with the local Floodplain Administrator?	The floodplain impacts were discussed at a meeting of MDOT Statewide Environmental Permit Coordinators and Resource Specialists. This level of analysis is adequate for draft EA purposes and the regulatory agency will be involved, as necessary, prior to the project being finalized.
114	64	3.11	3	Agencies should be changed to Agency. A flood plain map that shows the flood plain and the floodway with the proposed action should be included to support the discussion.	Revised draft EA (Appendix H)

115	64	3.12	1	See US Department of Agriculture NRSC letter, dated September 3, 2009, signed by Steve Olds. Update needed since this Agency requested follow up. See Appendix D-7	The following is an excerpt directly from the September 2009 NRCS Letter - "Some prime and farmland of local importance would be impacted by the project. <u>If the project proceeds</u>, I would urge you to utilize NRCS standards and specifications for conservation practices..." The draft EA is still in process and cannot proceed until that process is completed. Revised draft EA to clarify. As soon as this draft EA is finalized, the regulatory agencies will be contacted in writing and given the opportunity to review, comment and/or update their instructions.
116	66	3.14	1	Last sentence: delete "within the light lane"	Revised draft EA
117	66	3.14	2	Second sentence: Wouldn't these impacts be noted here? Where else would they be noted?	Revised draft EA
118	67	3.17		Why is this a separate section, as it is not an impact category?	Hazardous Waste Sites are an impact category under 1050.1E. (Addressed by Comment No. 73.)
119	67	3.18	1	Change to ASTM International Standard 1527-13	Revised draft EA
120	68	3.18	2	Last sentence: Add that any contamination encountered would be characterized and handled in accordance with state regulations	This language is already included later in the "Consequences of the Preferred Alternative" paragraph of Section 3.18 as appropriate.
121	69	4		The title of this section sounds like Section 3. What is the purpose of this section? Recommend changing the title to mitigation.	Revised draft EA
122	69	4	-	Title should be changed to Mitigation. EC was included in the previous section	Revised draft EA
123	-	-	-	In regard to the comment concerning Wildlife Hazards. The existence of the various nature features and species of concern should be assessed and part of the EA. FAA does not agree with the position that changing the profile of the airport will not change the relationship to the wildlife and their use of attractants. Only a certified Airport Wildlife Biologist is qualified to make that determination. The response to previous comment did not cite the participation of a certified Airport Wildlife Biologist.	This comment was not included in the revised draft EA, however it was included in the Response to Comments (Appendix K) . MDOT-AERO did consult with a certified Airport Wildlife Biologist from USDA when preparing the Response to Comments.
124	69	4.2.1	1	Last sentence: Does Audubon agree with this?	Revised draft EA
125	70	4.2.2	1	What about BMPs for air and water quality?	Addressed in Consequences of Preferred Alternative Sections of their respective impact categories.
126	71	5	1	The last public meeting was held six years ago; a new meeting will be needed.	This language is already included later in Section 5.2.2 Public Hearing.
127	71	5.1	1	What were the agencies' comments, at least in summary? What was MDOT's response?	Agency comments are provided in Appendix D and MDOT Responses are provided in Appendix K.
128	71	5.1	3	What did the local tribes say? Provide a summary.	Agency comments are provided in Appendix D and MDOT Responses are provided in Appendix K.
129	72	5.2.2	4	Add that another public meeting will be held.	This language was already included in the last paragraph of Section 5.2.2. Revised draft EA to clarify.

Subject: Draft Environmental Assessment for Ann Arbor Municipal Airport
Federal Aviation Administration Review Comments

Dear Ms. Lamrouex:

We have completed a review of the draft Environmental Assessment (EA) submitted to the Federal Aviation Administration (FAA) Detroit Airports District Office (ADO). Based on our review the FAA offers the following.

Air Traffic offers the following comments:

No comments.

Tech Ops offers the following comments:

Cover sheet. If the document is to be accepted as a federal document the coversheet will need to reflect this.

Section 2.1. Second bullet states "Shift and extend the parallel taxiway to coincide with the revised Runway 6/24". We recommend *revised* be changed to *extended*.

Section 2.2. This section does not appear to clearly state the need for the proposed action. Are the bulleted "objectives of the proposed project" actually proposed actions? The last bullet states "Relocate and potentially upgrade the Runway 24 Approach Light System". When will it be known if the approach light system will be replaced or upgraded? What is this dependent on? The remainder of the document deals with the impact of the runway extension, but does not address impacts related to the relocation of the existing light system or an upgrade to a new system. Also, action associated with Runway End Identifier Lights (REIL) is mentioned later in Section 4.17 and should be listed here as a proposed action. Are there any other NAVAIDs moving or being established?

Section 2.2.1. This section states that the Medium Intensity Approach Lighting System with Sequenced Flashers (MALSF) would serve the same function as the Omni-Directional Approach Lighting System (ODALS) and is structurally very similar. How would the footprint of the MALSF structures compare to the ODALS? What environmental impacts would installation of a MALSF create?

Section 3.1.2. We suggest adding a qualifier in the second paragraph to state the following: "...would be greater than those expected with the *proposed* expansion of ARB in its current location."

Section 4.4. The Consequences of the Preferred Alternative section states: "Comparisons of existing conditions at various airports with future build out conditions indicate that the net change in air emission is still below standards." Do these *conditions* include runway extension projects similar to the proposed action at ARB?

This section additionally states: "Consequently, the air model results for the Preferred Alternative would be identical to those for the No Build Condition." This statement implies that no air emissions would result from the proposed action. Is this accurate?

Section 4.5.1. Would the existing Storm Water Pollution Prevention Program cover the additional impervious surface area?

Section 4.5.2. We would recommend rewording the first sentence of the Consequences of the Preferred Alternative section to the following (if true and appropriate): *Surface and subsurface geological conditions would not be impacted by the Preferred Alternative.*

<u>Flight Procedures offers the following comments;</u>

No comments were provided by Flight Procedures Office (FPO).

However, it should be noted that the FPO must be notified by formal letter to request the development of future approach procedures for the relocated runway end coordinates. Information needed includes identification of when construction will start, finish, when the equipment will be relocated, etc. This information is critical for developing/amending approach procedures. The FPO must know the project phasing in order to have procedures ready when construction is complete. (Equipment relocation, threshold displacements, etc). Changes in runway pavement length will result in survey data. Please note that survey data must meet the specifications outlined in Advisory Circulars 150/5300-16, 17, and 18. Third party surveys must be coordinated with the FPO. The proponent must submit Proposed Equipment Relocation Data along with information related to any equipment that will be relocated or added to AVN-210 and ATA-110. 7. Publication of new/amended Approach Procedures could take from 18 months to 2 years after runway data is submitted to AVN-210 and ATA-110. NOTE: Development of Approach Procedures will not begin until an official letter of request for development of procedures is received by FPO and the proposed runway data and equipment data provided to AVN-210 and ATA-110. Proponent must update the airport FAA Form 5010-1 to reflect new runway data and updated runway changes.

<u>Airports Division offers the following comments;</u>

The report is not clear if there is a federal action being requested.

Based on the information contained within the draft EA it appears that at least two federal actions are being requested. These actions include the relocation or replacement of the current approach lighting system as well as the development for future approach procedures for the new runway end locations. The FAA recommends that these actions be clearly identified throughout the document. The first page of the document states that this draft EA will become a State of Michigan document when signed by the State Official and does not include similar language for the Federal Aviation Administration although there is a signature line included for a federal official. Please refer to FAA Order 5050.4B section 707(f).

Section 1 page 1-1. The draft EA states that the projects under consideration are those shown on the FAA approved Airport Layout Plan (ALP). This statement should be clarified as to the role of Michigan Department of Transportation (MDOT) in conditionally approving the ALP set on behalf of the FAA under the authority of the State Block Grant Program. When referencing the ALP throughout the document, additional emphasis should be made to the June 23, 2008 ALP approval letter that clearly states that the approval is conditional. Several conditions were placed on the approval letter including the requirements that the projects contained within the ALP set must comply with the National Environmental Policy Act (NEPA). The FAA recommends inclusion of the conditional ALP approval letter in the draft EA for disclosure purposes.

We also suggest the executive summary clearly outline who will be responsible for actions associated with the proposed project (i.e. local sponsor, local unit of government, State of Michigan, Federal Government). For the FAA to co-sign the document, the requested Federal Actions must be clearly identified within the executive summary and throughout the document where appropriate.

Section 2 page 2-1. References to the ALP set need to clarify that MDOT has only conditionally approved the ALP.

Section 2.2 page 2-4. The classification of a B-II Small Aircraft has been determined with a reference to MDOT 2009. Is the B-II "Small Aircraft" a designation that is contained within MDOT planning guidance? The FAA is not familiar with the classification of "small" when identifying the critical design aircraft for an airport. Please clarify how this distinction was derived.

Section 2.2 page 2-4. The paragraph discussing Origin-Destination Analysis should be expanded (or references made where information can be reviewed) to provide clarification to the general statements that are made. Specifically, is there a list of destinations that can be provided that will substantiate the need for a runway extension? A listing of destinations may aid the reader in putting the proposed project into perspective and may further substantiate the need for a runway extension. The report states that a significant number of operations occur between ARB and distant locations without quantifying the number and types of operations that are being referenced. The FAA recommends this be clarified in the report or referenced to the appropriate appendices.

Section 2.2 page 2-5. Are the bulleted items for the objectives of the proposed project presented in order of relative importance?

The statement that the project will enhance interstate commerce does not appear to be substantiated by supporting documentation here or elsewhere in the document. How has this been verified? What are the enhancements? Is this a need for the project? The FAA recommends referring to FAA Orders and Advisory Circulars that address runway length, operational capacity of the aircraft utilizing ARB, and any deficiencies that currently exist at ARB that are a function of the current runway length. Without a detailed discussion and explanation of what the interstate commerce enhancement is and how this has been quantified as a current need, the FAA does not recognize this as a need for the project based on the information provided.

If enhancing interstate commerce is a stated need for the project then the report should be expanded to include a full range of alternatives that can address this need including alternative modes of transportation as an example.

The last bulleted objective in this section is for the relocation and potential upgrade of the Runway 24 approach lighting system. The report does not appear to document why this is a need for the project or if the approach lighting system is currently required or needed in the future.

What benefit does the current approach lighting system provide the airport? There does not appear to be a credit for a reduction in minimums at the airport as a result of having the ODALS. Has a Benefit Cost Analysis (BCA) been completed or requested of the FAA substantiating the need for relocating or replacing the ODALS? Depending on the results of the BCA and associated justification for relocating the existing or installing a replacement light lane at ARB, the potential exists that the Federal Action may be limited to abandoning the existing ODALS and no relocation or replacement would occur with federal funds.

Section 2.2.1 page 2-5. The first paragraph implies that runway incursions have been occurring at ARB as a result of issues with the current line of sight between the ATCT and a portion of the taxiway system and taxiway hold area. The report further indicates that the proposed project will possibly prevent incursions from occurring. Are there any documented runway incursions resulting from the current line of sight issue that can be included in the report to substantiate this claim? The FAA supports safety enhancement projects and would consider this a measure to improve the line of sight from the ATCT to parallel taxiway and the hold area if it can be demonstrated that the existing condition contributes to runway incursions. While a goal of the FAA is to reduce the number of runway incursions at airports nationwide, the FAA can not definitively conclude that this proposed safety enhancement at ARB will potentially *prevent* runway incursions but rather if the line of sight issue is improved this may *reduce the possibility* of runway incursions.

This section includes discussion of the potential to achieve a clear 34:1 approach and reduce minimums at the airport. The ADO previously requested clarification on this issue in an e-mail dated March 4, 2010 (attached for reference). Based on the e-mail exchange, the FAA understands there is no anticipation of a reducing of minimums at this airport for the foreseeable planning future.

Since minimums will not be reduced as a result of the project, the FAA is unclear on the need for a 34:1 approach or how it enhances safety of the approach procedures currently published for the airport based on the existing 20:1 approaches. The document should better explain how providing a 34:1 approach enhances safety for the existing and future users at the airport or how this also may impact interstate commerce. Has the current 20:1 clear approach resulted in missed approaches that have been documented? If so how often does this condition occur?

Is providing clear 34:1 approaches a project need or a benefit that may result from the relocation of the runway? Earlier in the report it was identified as a stated objective, however, the discussion in the report does not appear to substantiate the need for this when combined with the e-mail exchange of March 4, 2010 and conditionally approved ALP dated June 23, 2008.

While the future 34:1 approaches are identified on the conditionally approved ALP, it should be noted that this would result in an expansion of the approach surface from the existing 500'x2,000'x5,000' to 500'x3,500'x10,000'. The EA needs to fully disclose the increase in the approach surface if a 34:1 approach is achieved and document any environmental impacts that result from the larger approach surface.

Section 2.2.2 page 2-6. It is not clear to the FAA why there is a summary of Wings of Mercy operations since 1992 including 51 flights reported in 2009. This data appears to be in addition to what was collected as part of the user survey report that relied predominately on information from calendar year 2007. What is the relevance of including the 2009 data or specifically identifying the Wings of Mercy flight operations? Are there a range of aircraft types that fly for Wings of Mercy? Does the proposed runway extension impact their operational capacity?

Section 2.2.2 page 2-7. Discussion on the Michigan State System Plan (MASP) identifies the airport reference code (ARC) as B-II. Does the MASP differentiate between B-II small and B-II large? In absence of a clearly defined category of B-II "small aircraft", the FAA would suggest simply referring to the airport with a B-II ARC.

Section 2.2.3 pages 2-7 and 2-8. This section most clearly identifies why a runway extension is being proposed in accordance with FAA advisory circulars and State standards outlined in the 2008 MASP. This section, in combination with section 2.2.4 that documents substantial use (i.e. over 500 annual operations) by the B-II critical design family of aircraft appears to substantiate the justification for the runway extension based on the 2007 operational data.

Section 2.2.4 page 2-9. Detailed operational information is presented for calendar year 2007. Subsequent years are generalized based on trend analysis and overall decrease in operations as reported in the FAA Terminal Area Forecast (TAF). There does not appear to be an evaluation to account for the 21.8% decrease in operations between 2007 and 2009. Would it be prudent to verify if the operational decrease impacted one user group more than other user groups? Are the numbers of local and itinerant operations decreasing at the same rate or is one segment impacted to a greater extent? This evaluation may be accomplished through additional user survey data collection or potentially from the ATCT located at ARB for subsequent years since 2007. Additionally, the FAA recommends that the year of the TAF being utilized for this report be identified.

Section 2.2.4 page 2-11. Specific information for AvFuel Corporation is presented to validate assumptions for the continued classification of the airport as B-II. It should be noted that AvFuel bases a Citation 560 Excel jet at ARB and is designated in the report as a B-II "*Large*" aircraft. The discussion further indicates that the Chief Pilot submitted written documentation regarding potential future operational levels at ARB. The written documentation does not appear to be included within the report or appendices. However, according to the text in the report, the Chief Pilot anticipates future operational levels increasing to 350-450 annual operations. This level of use, in combination with a limited number of additional similar B-II aircraft would appear to classify the airport as a B-II "*Large*" designation. The FAA reiterates the hesitation on identification of either a "small" or "large" within an airport reference code and recommends that any qualifier to the size of the B-II critical design aircraft be removed from the report. The number of operations forecasted to occur by AvFuel Corporation would further support the elimination of the qualifier as "small" to the ARC.

Section 2.2.6 page 2-12. The local objective of reducing runway overrun incidents appears to conclude that if the added runway length were present, all the incidents would have been avoided. Based on information presented, the FAA does not necessarily come to the same conclusion. There are many factors that go into any overrun incident and if additional runway length were present this may have only prolonged the overrun incident. The A-I category of aircraft involved with overrun incidents do not appear to have needed any length beyond the existing runway length to operate at full capacity and in a safe manner.

The paragraph that references Accelerated Stop Distance Available (ASDA) requirements appear to include fleet mixes other than A-I and implies that aircraft can accommodate their operational requirements with a reduced load capacity. The ADO is not aware of any A-I aircraft operating at ARB that would need to operate at a reduced load capacity to adequately satisfy their calculations for safely operating at ARB.

It is not clear when the 11 overrun incidents occurred, their cause, or conclusions that support that runway length was a factor in the overrun incidents. Can additional information be provided to support this position? If additional information is not available the FAA recommends removing this section from the document.

The FAA recognizes that this section of the report was included as a local objective and it is clearly and appropriately stated that the FAA does not recognize this as a need for extending the runway at ARB.

Section 2.2.7 page 2-12. The first bullet point indicates that additional runway length will allow for the majority of B-II "small" aircraft to operate without load restrictions. Has it been documented that the current B-II "small" users operate with load restrictions? If so, how often does this occur and what are the quantifiable impacts to their operations?

The third bullet implies that operational safety will be improved with a clear 34:1 approach. Currently the airport has LPV approaches with minimums of 300' and 1 mile. The ADO questions if a flatter approach is warranted in absence of reducing minimums as indicated in the March 4, 2010 e-mail correspondence. The discussion on the 34:1 approach should be re-evaluated and its need clearly identified. Currently the report does not seem to substantiate a need for a 34:1 approach if minimums are not anticipated to be lowered.

Section 3 page 3-1. The report indicates that alternatives were developed to meet the goals of ARB. These goals are to improve safety and efficiency and serve current users. These goals do not appear to be consistent with those previously outlined in the bullet points of section 2.2 (purpose and need). This section should refer to the stated needs and evaluate the alternatives ability to meet those needs.

Section 3.1.3 pages 3-3 and 3-4. There is discussion on extending the runway to the east and a listing of items impacted by pursuing this alternative. There is, however, no conclusion or statement that this option either should be, or was, eliminated. It can be inferred later in the report by the absence of this alternative that it was eliminated but the conclusion as to why it has been eliminated has not been stated.

When addressing the FAA's comments (included within this letter) associated with the stated needs for the project earlier in the report, the responses to these comments may influence the conclusions on why some of the alternatives carried forward have been eliminated. Specifically, if needs stated in section 2.2 are not further substantiated, or it is concluded that one or more of the needs do not exist, additional alternatives may need to be carried forward if they adequately address the needs for the project. The FAA will re-evaluate the conclusions of the alternatives section once the FAA's comments on the purpose and need section are addressed.

Section 3.3 page 3-8. Based on the Information presented in the draft EA, the FAA has not reached the same conclusion that alternatives 1 and 2 do not meet the stated needs for the project. An apparent evaluation parameter for alternative 2 included in section 3.3.3 discusses the tower line of sight. This evaluation matrix does not appear to be consistent with those goals stated in Section 3 on page 3-1. The previous comment on the apparent disconnect between the different sections of the report also applies to the specific alternative evaluation. The FAA recommends that the decision matrix for which alternatives were eliminated be clarified in the EA.

Table 3-1 page 3-8. The table appears to incorrectly dismiss alternative 1 because it does not meet purpose and need. .The discussion in 3.3.2 does not support that conclusion. Additionally, there is reference to a future expansion of State Road. This appears to be the first reference to this issue. Is this a need for the State Road expansion project? In what time frame is the State Road expansion project expected to occur? Should there be expanded discussion on other regional planning projects in this EA so the public can better understand the different parameters that ARB is confined to or bound by?

Additional alternatives that may be considered for evaluation to address the need statements could include a combination of items such as: alternative modes of transportation to address enhancing interstate commerce, removal or relocation of obstructions that limit the ATCT line of sight issues, and raising or constructing a new ATCT to address the line of sight issues. Have any previous discussion on additional alternatives been eliminated prior to, or as part of the planning and environmental assessment process for ARB?

Section 3.4 page 3-9. This section contains a brief summary of environmental resources that will not be impacted by build alternative 3. Would it be advantageous to also summarize environmental impacts associated with the other build alternatives? There is a general statement regarding noise impact analysis in this section that identifies that the 65 DNL contour is not within 1,000 feet of any residential structure. What is the purpose for this statement? The FAA is not aware of an environmental impact decision matrix associated with the distance between residential structures and the 65 DNL.contour.

Section 4.3.5 page 4-17. The conclusion for the implementation of the preferred alternative states that a positive result of improvements is the ability of business owners to achieve improved fleet efficiency for critical aircraft by maximizing their passenger and/or cargo loads. How has this statement been substantiated? What records exist that current users at ARB are not operating at maximum passenger and/or cargo loads? What has been the economic impact of the reduction of loads if they are occurring?

Section 4.9 pages 4-22 and 4-23. State endangered and special concern species were identified at ARB. The sponsor appears to be proposing a mitigation effort to limit grading for the project to avoid breeding seasons for the specific species. Has this proposed mitigation plan been found to be acceptable by the resource agencies? There is reference to an Audubon Society agreement regarding mowing boundaries. Who is the agreement between? Has this agreement been reviewed by the environmental assessment preparation team? Are there limitations or restrictions for use of airport land as a result of this agreement? Has the Audubon Society been included or have they provided input to this draft EA?

Section 4-15 pages 4-24 and 4-25. The FAA recommends that the score from the USDA form AD 1006 be disclosed in this section and explain what the score means. The consequences identify that some prime and unique farmland of local importance are impacted by this project. The amount of prime and unique farmland should be quantified. Are there any mitigation requirements for this change in use?

Section 4-16 page 4-25. The report identified a decrease in facility energy usage with the installation of LED taxiway lights. Is this net decrease in energy usage compared to baseline or existing conditions?

Section 4.17 page 4-25. There is no discussion on potential relocation of the ODALS or replacement with upgraded equipment. Would there be impacts with either scenario (relocation or replacement)? It should also be noted that the potential exists for the current ODALS to be abandoned if a relocation or upgrade is not justified with a BCA.

Section 4.20 page 4-26. The evaluation regarding construction impacts in the draft EA do not appear to address staging areas during project implementation. The FAA recommends the report verify that staging areas will not impact environmental resources; and as necessary, outline any required mitigation measures for staging area impacts.

Section 4.21 page 4-26. Should the reference to ASTM Standard E1527-94 be updated to E1527-05? The EA should also state if the review was done in accordance with FAA Order 1050.19B, *"Environmental Due Diligence Audits"*.

Section 5 page 5-1. The FAA suggests that this section be titled *Mitigation* rather than *Environmental Consequences – Other Considerations*. We also question if it is prudent to discuss noise, social impacts and community disruption, wetland impacts, and threatened and endangered species in this section since there appear to be no mitigation requirements associated with any of these categories. The FAA suggests either listing all environmental categories reviewed that do not require mitigation or not list any of the categories that do not have required mitigation. Is it a true statement that there are no mitigation measures for threatened and endangered species? Section 4.9 appears to indicate there are seasonal limitations on when grading will occur.

Would it be better to outline required permits for the project in this section, best management practices, construction requirements, etc. rather than having a discussion on what mitigation measures are not required?

Section 6.2.1 pages 6-1 and 6-2. This section includes a summary of when Citizen's Advisory Committee (CAC) meetings were held and the overall agenda for each meeting. The EA does not document either in the text or in an appendix what issues may have been raised and how they were addressed in the CAC meetings. The FAA suggests additional information from the CAC meetings be included in the EA.

Section 6.2.2, page 6-2. The last sentence of this section should indicate that comments received will be reviewed, summarized, and addressed.

Section 7 page 7-3. This section identifies a request that the state and federal agencies approve a Finding of No Significant Impact. This is the first location in the document that specifically requests a federal action. As discussed previously, the FAA requests that earlier in the document the specific actions being requested of each agency be outlined. Based on the review of this document the FAA anticipates that the FAA will be requested to evaluate, and as appropriate, abandon/relocate/replace the existing approach lighting system and develop new flight procedures for the new runway end locations.

Next steps.

The draft EA appears to be intended to be a jointly executed document by both MDOT and the FAA. Since there are several updates/clarifications requested by the FAA contained in this letter and the sponsor's responses may be substantial, it would be prudent to afford the public an additional opportunity to review and comment on the changes that are anticipated to be made for the final draft publication. Most specifically, the document will need to clearly outline the requested local, state and federal actions. Since this was not clearly presented in the initial draft EA, the FAA may consider these changes and clarifications as a material change to the document that should result in solicitation of additional public comment. This may be accomplished by an additional public information meeting or public hearing.

Once the FAA receives confirmation that the above comments have been addressed in the form of an updated draft EA, the FAA requests that we be allotted sufficient time to review, comment, and potentially concur with the updates prior to making the document available to the public for further comment.

If you desire further clarification of these comments, please contact me at (734) 229-2916.

Sincerely,

Brad N. Davidson, P.E.
Community Planner/Environmental Protection Specialist

Federal Aviation Administration

Advisory Circular

Subject: RUNWAY LENGTH REQUIREMENTS FOR AIRPORT DESIGN	**Date:** 7/1/2005 **Initiated by:** AAS-100	**AC No:** 150/5325-4B **Change:**

1. PURPOSE. This Advisory Circular (AC) provides guidelines for airport designers and planners to determine recommended runway lengths for new runways or extensions to existing runways.

2. CANCELLATION. This AC cancels AC 150/5325-4A.

3. APPLICATION. The standards and guidelines contained in this AC are recommended by the Federal Aviation Administration strictly for use in the design of civil airports. The guidelines, the airplane performance data curves and tables, and the referenced airplane manufacturer manuals *are not to be used* as a substitute for flight planning calculations as required by airplane operating rules. For airport projects receiving Federal funding, the use of this AC is mandatory.

David L. Bennett
Director, Office of Airport Safety and Standards

CHAPTER 1. INTRODUCTION

101. BACKGROUND. Airplanes today operate on a wide range of *available* runway lengths. Various factors, in turn, govern the *suitability* of those available runway lengths, most notably airport elevation above mean sea level, temperature, wind velocity, airplane operating weights, takeoff and landing flap settings, runway surface condition (dry or wet), effective runway gradient, presence of obstructions in the vicinity of the airport, and, if any, locally imposed noise abatement restrictions or other prohibitions. Of these factors, certain ones have an operational impact on available runway lengths. That is, for a given runway the usable length made available by the airport authority may not be entirely *suitable* for all types of airplane operations. Fortunately, airport authorities, airport designers, and planners are able to mitigate some of these factors. For example, runways designed with longitudinal profiles equaling zero slope avoid required runway length adjustments. Independently, airport authorities working with their local lawmakers can establish zoning laws to prohibit the introduction of natural growth and man-made structural obstructions that penetrate existing or planned runway approach and departure surfaces. Effective zoning laws avoid the displacement of runway thresholds or reduction of takeoff runway lengths thereby providing airplanes with sufficient clearances over obstructions during climb outs. Airport authorities working with airport designers and planners should validate future runway demand by identifying the critical design airplanes. In particular, it is recommended that the evaluation process assess and verify the airport's ultimate development plan for realistic changes that could result in future operational limitations to customers. In summary, the goal is to construct an available runway length for new runways or extensions to existing runways that is suitable for the forecasted critical design airplanes.

102. DETERMINING RECOMMENDED RUNWAY LENGTHS.

a. Assumptions and Definitions.

(1) Design Assumptions. The assumptions used by this AC are approaches and departures with no obstructions, zero wind, dry runway surfaces, and zero effective runway gradient. Assumptions relative to airplane characteristics are described within the applicable chapter of this AC.

(2) Critical Design Airplanes. The listing of airplanes (or a single airplane) that results in the longest recommended runway length. The listed airplanes will be evaluated either individually or as a single family grouping to obtain a recommended runway length.

(3) Small Airplane. An airplane of 12,500 pounds (5,670 kg) or less maximum certificated takeoff weight.

(4) Large Airplane. An airplane of more than 12,500 pounds (5,670 kg) maximum certificated takeoff weight.

(5) Maximum Certificated Takeoff Weight (MTOW). The maximum certificated weight for the airplane at takeoff, i.e., the airplane's weight at the start of the takeoff run.

(6) Regional Jets. Although there is no regulatory definition for a regional jet (RJ), an RJ for this advisory circular is a commercial jet airplane that carries fewer than 100 passengers.

(7) Crosswind Runway. An additional runway built to compensate primary runways that provide less than the recommended 95 percent wind coverage for the airplanes forecasted to use the airport.

(8) Substantial Use Threshold. Federally funded projects require that critical design airplanes have at least 500 or more annual itinerant operations at the airport (landings and takeoffs are considered as separate operations) for an individual airplane or a family grouping of airplanes. Under unusual circumstances, adjustments may be made to the 500 total annual itinerant operations threshold after considering the circumstances of a particular airport. Two examples are airports with demonstrated seasonal traffic variations, or airports situated in isolated or remote areas that have special needs.

(9) Itinerant Operation. Takeoff or landing operations of airplanes going from one airport to another airport that involves a trip of at least 20 miles. Local operations are excluded.

(10) Effective Runway Gradient. The difference between the highest and lowest elevations of the runway centerline divided by the runway length.

b. Procedure and Rationale for Determining Recommended Runway Lengths. This AC uses a five-step procedure to determine recommended runway lengths for a selected list of critical design airplanes. As previously stated, the information derived from this five-step procedure is for airport design and is not to be used for flight operations. Flight operations must be conducted per the applicable flight manual. The five steps and their rationale are as follows:

(1) Step #1. Identify the list of critical design airplanes that will make regular use of the proposed runway for an established planning period of at least five years. For Federally funded projects, the definition of the term "*substantial use*" quantifies the term "regular use" (see paragraph 102a(8).)

(2) Step #2. Identify the airplanes that will require the longest runway lengths at maximum certificated takeoff weight (MTOW). This will be used to determine the method for establishing the recommended runway length. Except for regional jets, when the MTOW of listed airplanes is 60,000 pounds (27,200 kg) or less, the recommended runway length is determined according to a *family grouping of airplanes* having similar performance characteristics and operating weights. Although a number of regional jets have an MTOW less than 60,000 pounds (27,200 kg), the exception acknowledges the long range capability of the regional jets and the necessity to offer regional jet operators the flexibility to interchange regional jet models according to passenger demand without suffering operating weight restrictions. When the MTOW of listed airplanes is over 60,000 pounds (27,200 kg), the recommended runway length is determined according to *individual airplanes*. The recommended runway length in the latter case is a function of the most critical individual airplane's takeoff and landing operating weights, which depend on wing flap settings, airport elevation and temperature, runway surface conditions (dry or wet), and effective runway gradient. The procedure assumes that there are no obstructions that would preclude the use of the full length of the runway.

(3) Step #3. Use table 1-1 and the airplanes identified in step #2 to determine the method that will be used for establishing the recommended runway length. Table 1-1 categorizes *potential design airplanes* according to their MTOWs. MTOW is used because of the significant role played by airplane operating weights in determining runway lengths. As seen from table 1-1, the first column separates the various airplanes into one of three weight categories. Small airplanes, defined as airplanes with MTOW of 12,500 pounds (5,670 kg) or less, are further subdivided according to approach speeds and passenger seating as explained in chapter 2. Regional jets are assigned to the same category as airplanes with a MTOW over 60,000 pounds (27,200 kg). The second column identifies the applicable airport design approach (by airplane family group or by individual airplanes) as noted previously in step #2. The third column directs the airport designer to the appropriate chapter for design guidelines and whether to use the referenced tables contained in the AC or to obtain airplane manufacturers' airport planning manuals (APM) for each individual airplane under evaluation. In the later case, APMs provide the takeoff and landing runway lengths that an airport designer will in turn apply to the associated guidelines set forth by this AC to obtain runway lengths. The airport designer should be aware that APMs go by a variety of names. For example, Airbus, the Boeing Company, and Bombardier respectively title their APMs as "Airplane Characteristics for Airport Planning," "Airplane Characteristics for Airport Planning," and "Airport Planning Manuals." For the purpose of this AC, the variously titled documents will be referred to as APM. Appendix 1 lists the websites of the various airplane manufacturers to provide individuals a starting point to retrieve an APM or a point of contact for further consultation.

(4) Step #4. Select the recommended runway length from among the various runway lengths generated by step #3 per the process identified in chapters 2, 3, or 4, as applicable.

(5) Step #5. Apply any necessary adjustment to the obtained runway length, when instructed by the applicable chapter of this AC, to the runway length generated by step #4 to obtain a final recommended runway length. For instance, an adjustment to the length may be necessary for runways with non-zero effective gradients. Chapter 5 provides the rationale for these length adjustments.

Table 1-1. Airplane Weight Categorization for Runway Length Requirements

Airplane Weight Category Maximum Certificated Takeoff Weight (MTOW)			Design Approach	Location of Design Guidelines
12,500 pounds (5,670 kg) or less	Approach Speeds less than 30 knots		Family grouping of small airplanes	Chapter 2; Paragraph 203
	Approach Speeds of at least 30 knots but less than 50 knots		Family grouping of small airplanes	Chapter 2; Paragraph 204
	Approach Speeds of 50 knots or more	With Less than 10 Passengers	Family grouping of small airplanes	Chapter 2; Paragraph 205 Figure 2-1
		With 10 or more Passengers	Family grouping of small airplanes	Chapter 2; Paragraph 205 Figure 2-2
Over 12,500 pounds (5,670 kg) but less than 60,000 pounds (27,200 kg)			Family grouping of large airplanes	Chapter 3; Figures 3-1 or 3-2 [1] and Tables 3-1 or 3-2
60,000 pounds (27,200 kg) or more or Regional Jets [2]			Individual large airplane	Chapter 4; Airplane Manufacturer Websites (Appendix 1)

Note [1]: When the design airplane's APM shows a longer runway length than what is shown in figure 3-2, use the airplane manufacturer's APM. However, users of an APM are to adhere to the design guidelines found in Chapter 4.

Note [2]: All regional jets regardless of their MTOW are assigned to the 60,000 pounds (27,200 kg) or more weight category.

103. PRIMARY RUNWAYS. The majority of airports provide a single primary runway. Airport authorities, in certain cases, require two or more primary runways as a means of achieving specific airport operational objectives. The most common operational objectives are to (1) better manage the existing traffic volume that exceed the capacity capabilities of the existing primary runway, (2) accommodate forecasted growth that will exceed the current capacity capabilities of the existing primary runway, and (3) mitigate noise impacts associated with the existing primary runway. Additional primary runways for capacity justification are parallel to and equal in length to the existing primary runway, unless they are intended for smaller airplanes. Refer to AC 150/5060-5, *Airport Capacity and Delay,* for additional discussion on runway usage for capacity gains. Another common practice is to assign individual primary runways to different airplane classes, such as, separating general aviation from non-general aviation customers, as a means to increase the airport's efficiency. The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions. For Federally funded projects, the criterion for substantial use applies (see paragraph 102a(8).) The design objective for additional primary runways is shown in table 1-2. The table takes into account the separation of airplane classes into distinct airplane groups to achieve greater airport utilization. Procedurally, follow the guidelines found in subparagraph 102(b) for determining recommended runway lengths for primary runways, and, for additional primary runways, apply table 1-2.

104. CROSSWIND RUNWAYS. The design objective to orient primary runways to capture 95 percent of the crosswind component perpendicular to the runway centerline for any airplane forecast to use the airport is not always achievable. In cases where this cannot be done, a crosswind runway is recommended to achieve the design standard provided in AC 150/5300-13, *Airport Design,* for allowable crosswind components according to airplane design groups. Even when the 95-percentage crosswind coverage standard is achieved for the design airplane or airplane design group, cases arise where certain airplanes with lower crosswind capabilities are unable to utilize the primary runway. For airplanes with lesser crosswind capabilities, a crosswind runway may be built, provided there is regular usage. For Federally funded projects, the criterion for substantial use applies to the airplane used as the design airplane needing the crosswind runway (see paragraph 102a(8).) The design objective for the length of crosswind runways is shown in table 1-3. Procedurally, follow the guidelines found in subparagraph 102(b) for determining recommended runway lengths for crosswind runways, and, for additional crosswind runways, apply table 1-3.

Table 1-2. Runway Length for Additional Primary Runways

Runway Service Type, User	Runway Length for Additional Primary Runway Equals
Capacity Justification, Noise Mitigation, Regional Jet Service	100 % of the primary runway
Separating Airplane Classes - Commuter, Turboprop, General Aviation, Air Taxis	Recommended runway length for the less demanding airplane design group or individual design airplane

Table 1-3. Runway Length for Crosswind Runway

Runway Service	Runway Length for Crosswind Runway Equals
Scheduled [1] Such as Commercial Service Airports	100 % of primary runway length when built for the same individual design airplane or airplane design group that uses the primary runway
	100% of the recommended runway length determined for the lower crosswind capable airplanes using the primary runway
Non-Scheduled [2] Such as General Aviation Airports	100% of the recommended runway length determined for the lower crosswind capable airplanes using the primary runway

Note [1]: Transport service operated over routes pursuant to published flight schedules that are openly advertised with dates or times (or both) or otherwise made readily available to the general public or pursuant to mail contracts with the U.S. Postal Service (Bureau of Transportation Statistics, Department of Transportation (DOT)).

Note [2]: Revenue flights, such as charter flights that are not operated in regular scheduled service, and all non-revenue flights incident to such flights (Bureau of Transportation Statistics, DOT). For Federally funded programs, such as AIP, there must be at least 500 annual itinerant operations and 100% of the class.

105. RUNWAY LENGTH BASED ON DECLARED DISTANCES CONCEPT. The application of the declared distances concept to overcome safety deficiencies is not intended for new runways. New runways must meet design standards when constructed. See AC 150/5300-13, appendix 14, for information related to declared distances.

106. COMPUTER PROGRAM. The airport design software cited in Appendix 11 of AC 150/5300-13, Airport Design for Microcomputers (AD42D.EXE), was developed for airport planners to facilitate in the planning of airport layouts. The computer program only provides estimates instead of actual length requirements. The design software is available at http://www.faa.gov/airports_airtraffic/airports/construction/.

107. SELECTED 14 CODE OF FEDERAL REGULATIONS CONCERNING RUNWAY LENGTH REQUIREMENTS. Appendix 2 provides a list of selected 14 Code of Federal Regulations that address the airworthiness certification and operational requirements of airplanes associated with runway length.

CHAPTER 2. RUNWAY LENGTHS FOR SMALL AIRPLANES WITH MAXIMUM CERTIFICATED TAKEOFF WEIGHT OF 12,500 POUNDS (5,670 KG) OR LESS

201. DESIGN GUIDELINES. The design procedure for small airplanes requires the following information: the critical design airplanes under evaluation, approach speed in knots (1.3 x stall speed), number of passenger seats, airport elevation above mean sea level, and the mean daily maximum temperature of the hottest month at the airport. Once obtained, apply the guidance from the appropriate paragraph below to obtain the recommended runway length. For this airplane weight category, no further adjustment to the obtained length from the figures 2.1 or 2.2 is necessary. For example, there is no operational requirement to take into account the effect of effective runway gradient for takeoff or landing performance.

202. DESIGN APPROACH. For purposes of design, this AC provides a design concept for airports that serve only airplanes with a maximum certificated takeoff weight of 12,500 pounds (5,670 kg) or less. The design concept starts by grouping all small airplanes, that is, the critical design airplanes, according to approach speed. The highest approach speed group is divided on the basis of passenger seats, namely, “airplanes having fewer than 10 passenger seats” as compared to “airplanes having 10 or more passenger seats.” The less than 10 passenger seats category is further based on two percentages of fleet, namely, “95 percent of the fleet” or “100 percent of the fleet” categories, as explained in paragraph 205. For these airplanes, figures 2-1 and 2-2 show only a single curve that takes into account the most demanding operations to obtain the recommended runway length. Although both figures pertain mainly to small propeller driven airplanes, figure 2-2 does include small turbo-powered airplanes. Airport designers can, instead of applying the small airplane design concept, determine the recommended runway length from airplane flight manuals for the airplanes to be accommodated by the airport in lieu of the runway length curves depicted in figures 2-1 or 2-2. For example, owners of multi-engine airplanes may require that their pilots use the airplane’s accelerate-stop distance in determining the length of runway available for takeoff.

203. SMALL AIRPLANES WITH APPROACH SPEEDS OF LESS THAN 30 KNOTS. Airplanes with approach speeds of less than 30 knots are considered to be short takeoff and landing or ultra light airplanes. Their recommended runway length is 300 feet (92 meters) at mean sea level. Runways located above mean sea level should be increased at the rate of 0.03 x airport elevation above mean sea level to obtain the recommended runway length at that elevation.

204. SMALL AIRPLANES WITH APPROACH SPEEDS OF 30 KNOTS OR MORE BUT LESS THAN 50 KNOTS. The recommended runway length is 800 feet (244 meters) at mean sea level. Runway lengths above mean sea level should be increased at the rate of 0.08 x airport elevation above mean sea level to obtain the recommended runway length at that elevation.

205. SMALL AIRPLANES WITH APPROACH SPEEDS OF 50 KNOTS OR MORE WITH MAXIMUM CERTIFICATED TAKEOFF WEIGHT OF 12,500 POUNDS (5,670 KG) OR LESS. Figures 2-1 and 2-2 provide the recommended runway lengths based on the seating capacity and the mean daily maximum temperature of the hottest month of the year at the airport. The fleet used in the development of the figures consisted of small airplanes certificated in the United States. Figure 2-1 categorizes small airplanes with less than 10 passenger seats (excludes pilot and co-pilot) into two family groupings according to “percent of fleet,” namely, 95 and 100 percent of the fleet. Figure 2-2 categorizes all small airplanes with 10 or more passenger seats into one family grouping. Figure 2-2 further alerts the airport designer that for airport elevations above 3,000 feet (914 m), that the airport designer must use the 100 percent of fleet chart of figure 2-1 instead of using figure 2-2. As shown, both figures provide examples that start with the horizontal temperature axis then, proceed vertically to the applicable airport elevation curve, followed by proceeding horizontally to the vertical axis to read the recommended runway length.

a. Selecting Percentage of Fleet for Figure 2-1. The differences between the two percentage categories are based on the airport’s location and the amount of existing or planned aviation activities. The airport designer should make the selection based on the following criteria.

(1) 95 Percent of Fleet. This category applies to airports that are primarily intended to serve medium size population communities with a diversity of usage and a greater potential for increased aviation activities. Also included in this category are those airports that are primarily intended to serve low-activity locations, small population communities, and remote recreational areas. Their inclusion recognizes that these airports in many cases develop into airports with higher levels of aviation activities.

(2) 100 Percent of Fleet. This type of airport is primarily intended to serve communities located on the fringe of a metropolitan area or a relatively large population remote from a metropolitan area.

b. Future Airport Expansion Considerations. Airports serving small airplanes remain fairly constant in terms of the types of small airplane using the airport and their associated operational requirements. However, it is recommended that the airport designer assess and verify the airport's ultimate development plan for realistic changes that, if overlooked, could result in future operational limitations to customers. The airport designer should at least assess and verify the impacts of:

(1) Expansions to accommodate airplanes of more than 12,500 pounds (5,670 kg). Failure to consider this change during an initial development phase may lead to the additional expense of reconstructing or relocating facilities in the future.

(2) Requirements to operate the runway during periods of Instrument Meteorological Conditions (IMC). The requirement for this capability is highest among airplanes used for business and air taxi purposes.

206. DEVELOPMENT OF THE RUNWAY LENGTH CURVES. 14 Code of Federal Regulations Part 23, *Airworthiness Standards: Normal, Utility, and Acrobatic Category Airplanes*, prescribes airworthiness standards for the issuance of small airplane type certificates. The performance information for each airplane (for example, as defined in *Section 23.51, Takeoff; Section 23.75, Landing; and Section 2.1587, Performance Information*) is contained in the individual airplane flight manual. This information is provided to assist the airplane operator in determining the runway length necessary to operate safely. Performance information from those manuals was selectively grouped and used to develop the runway length curves in figures 2-1 and 2-2. The major parameters utilized for the development of theses curves were the takeoff and landing distances for figure 2-1 and the takeoff, landing, and accelerate-stop distances for figure 2-2. The following conditions were used in developing the curves:

Zero headwind component.

Maximum certificated takeoff and landing weights.

Optimum flap setting for the shortest runway length (normal operation).

Airport elevation and temperature were left variable (values need to be obtained).

Other factors, such as relative humidity and effective runway gradient, also have a variable effect on runway length but are not accounted for in certification. However, these other factors were accounted for in the runway length curves by increasing the takeoff or landing distance (whichever was longer) of the group's most demanding airplane by 10 percent for the various combinations of elevation and temperature.

14 Code of Federal Regulations Part 135, *Operating Requirements: Commuter and On Demand Operations and Rules Governing Persons on Board such Aircraft*, imposes the operational requirements on those airplanes having a seating configuration of 10 passenger seats or more to include the accelerate-stop distance parameter in computing the required takeoff runway length. As previously mentioned, figure 2-2 includes the accelerate-stop distance parameter.

Figure 2-1. Small Airplanes with Fewer than 10 Passenger Seats
(Excludes Pilot and Co-pilot)

Example:

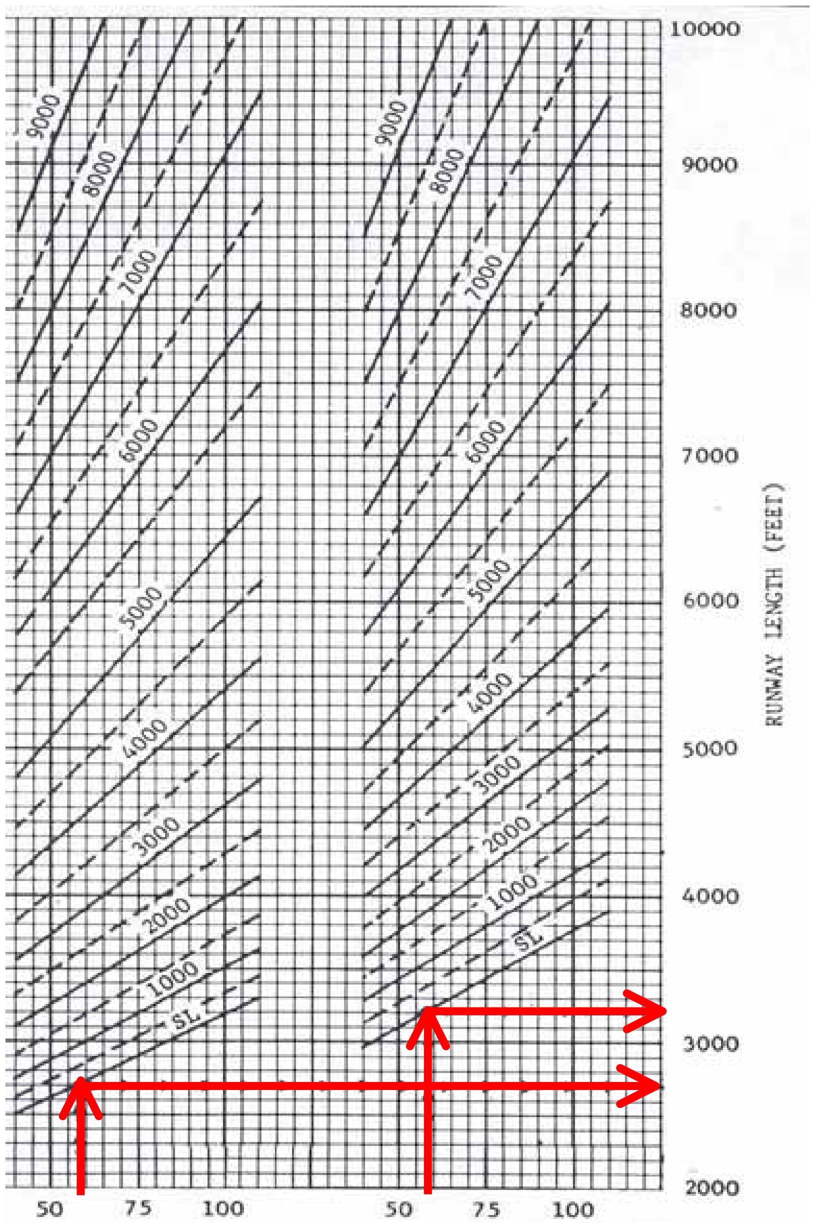
Temperature (mean day max hot month): 59° F (15° C)
Airport Elevation: Mean Sea Level

Note: Dashed lines shown in the table are mid values of adjacent solid lines.

Recommended Runway Length:

For 95% = 2,700 feet (823 m)
For 100% = 3,200 feet (975 m)

Airport Elevation
(feet)
95 Percent of Fleet 100 Percent of Fleet



Mean Daily Maximum Temperature of the Hottest Month of Year

(Excludes Pilot and Co-pilot)

Representative Airplanes	Runway Length Curves
Raytheon B80 Queen Air **Raytheon** E90 King Air **Raytheon** B99 Airliner **Raytheon** A100 King Air (Raytheon formerly Beech Aircraft) **Britten-Norman** Mark III-I Trilander **Mitsubishi** MU-2L **Swearigen** Merlin III-A **Swearigen** Merlin IV-A **Swearigen** Metro II	**Example:** Temperature (mean day max hot month) 90° F (32° C) Airport Elevation (msl) 1,000 feet (328 m) Recommended Runway Length 4,400 feet (1,341 m) **Note:** For airport elevations above 3,000 feet (915 m), use the 100 percent of fleet grouping in figure 2-1.  **(Degrees F)**

CHAPTER 3. RUNWAY LENGTHS FOR AIRPLANES WITHIN A MAXIMUM CERTIFICATED TAKEOFF WEIGHT OF MORE THAN 12,500 POUNDS (5,670 KG) UP TO AND INCLUDING 60,000 POUNDS (27,200 KG)

301. DESIGN GUIDELINES. The design procedure for this airplane weight category requires the following information: airport elevation above mean sea level, mean daily maximum temperature of the hottest month at the airport, the critical design airplanes under evaluation with their respective useful loads. Once obtained, apply either figure 3-1 or figure 3-2 to obtain a single runway length for the entire group of airplanes under evaluation. Finally, apply any landing or takeoff length adjustments, if necessary, to the resulting runway length to obtain the recommended runway length.

302. DESIGN APPROACH. The recommended runway length for this weight category of airplanes is based on performance curves (figures 3-1 and 3-2) developed from FAA-approved airplane flight manuals in accordance with the provisions of 14 Code of Federal Regulations Part 25, *Airworthiness Standards: Transport Category Airplanes,* and Part 91, *General Operating and Flight Rules*. If the airport is planned for operations that will include only turbojet-powered airplanes weighing under 60,000 pounds (27,200 kg) maximum certificated takeoff weight (MTOW) in conjunction with other small airplanes of 12,500 pounds (5,670 kg) or less, use the curves shown in either figures 3-1 or 3-2. To determine which of the two figures to apply, first use tables 3-1 and 3-2 to determine which one of the two “percentage of fleet” categories represents the critical design airplanes under evaluation. With that determination, then select either the “60 percent useful load” curves or the “90 percent useful load” curves on the basis of the haul lengths and service needs of the critical design airplanes. **Note:** at elevations over 5,000 feet (1,524 m) above mean sea level, the recommended runway length obtained for small airplanes from chapter 2 may be greater than those obtained by these figures. In this case, the requirements for the small airplanes govern. Finally, the curves of figures 3-1 and 3-2 apply to airport elevations up to 8,000 feet (2,439 m) above mean sea level. For higher elevations, consult the airplane manufacturer(s) for their recommendations.

303. PERCENTAGE OF FLEET AND USEFUL LOAD FACTOR. The curves in figure 3-1 and 3-2 are based on a grouping of only the turbojet-powered fleet (and business jets) according to performance capability as contained in the FAA-approved airplane manuals under an assumed loading condition. Interpolation is allowed only within *a single set of curves* (e.g., an elevation at 2,500 feet within the “75 percent of the fleet at 60 percent useful load” set of curves) but not valid *between sets of curves* (e.g., an 85 percent useful load between the set of curves “75 percent of the fleet at 60 percent useful load” and “75 percent of the fleet at 90 percent useful load.”) The restriction is because each set assumed a specific, non-variable loading condition. Figures 3-1 and 3-2 contain a set of two curves based upon the percentage of the fleet and the percentage of useful load that can be accommodated by the runway lengths obtained from the curves. For example, the “75 percent fleet at 60 percent useful load” curve provides a runway length *sufficient to satisfy the operational requirements* of approximately 75 percent of the fleet at 60 percent useful load. This figure is to be used for those airplanes operating with no more than a 60 percent useful load factor. Both figures 3-1 and 3-2 provide examples that start with the horizontal temperature axis, then proceed vertically to the airport elevation curve, and finally proceed horizontally to the vertical axis to obtain the runway length. The final step is to apply any necessary length adjustments to the obtained length in accordance with paragraph 304 to determine the recommended runway length.

a. Percentage of Fleet.

(1) Tables 3-1 and 3-2. Table 3-1 provides the list of those airplanes that comprise the “75 percent of fleet” category and therefore can be accommodated by the runway lengths resulting from figure 3-1. Table 3-2, provides the remaining airplanes beyond that of table 3-1 that comprise the “100 percent of fleet” category and therefore can be accommodated by the resulting runway lengths from figure 3-2. The distinction between the tables is that airplanes listed in table 3-2 require at least 5,000-foot (1,524 m) runways at mean sea level and at the standard day temperature of 59° F (15° C) (see paragraph 403 and table 4-1 for an explanation of the concept.). Airplanes listed in table 3-1 require less than 5,000 feet (1,524 m) for the same conditions.

(2) Selecting Figures 3-1 or 3-2. The airport designer must determine from which list the airplanes under evaluation are found. Use figure 3-1 when the airplanes under evaluation are not listed in table 3-2. If a relatively few airplanes under evaluation are listed in table 3-2, then figure 3-2 should be used to determine the runway length. If no adjustments to this length are necessary as outlined above, then this becomes the recommended runway length.

b. Useful Load Factor.

(1) The term *useful load factor* of an airplane for this AC is considered to be the difference between the maximum allowable structural gross weight and the operating empty weight. A typical operating empty weight includes the airplane's empty weight, crew, baggage, other crew supplies, removable passenger service equipment, removable emergency equipment, engine oil, and unusable fuel. In other words, the useful load then consists of passengers, cargo, and usable fuel. It is noted that although o*perating empty weight* varies considerably with individual airplanes, the curves used in the figures were based on the average operating empty weights of numerous business jets.

(2) Figures 3-1 and 3-2 provide only two useful load percentages, namely "60 percent useful load" and "90 percent useful load." Curves are not developed for operations at "100 percent useful load" because many of the airplanes used to develop the curves in figures 3-1 and 3-2 were operationally limited in the second segment of climb. That is, the allowable gross takeoff weight is often limited by ambient conditions of temperature and elevation to an operating weight that is less than their maximum structural gross weight. Therefore, APMs contain climb limitations when required. Because of the climb limitation, the runway length resulting from the "90 percent useful load" curves are considered by this AC to approximate the limit of beneficial returns for the runway. A specific list of business jets were used to obtain an average operating empty weight, which in turn, was used to develop the curves.

c. Privately Owned Business Jets. Business jets that are privately owned are included in their respective 75 percent and 100 percent of fleet categories.

d. Air Carrier Regional Jets. As previously mentioned, the recommended runway lengths for regional jets for air carrier service are addressed in chapter 4.

304. RUNWAY LENGTH ADJUSTMENTS. The runway lengths obtained from figures 3-1 and 3-2 are based on no wind, a dry runway surface, and zero *effective runway gradient*. Effective runway gradient is defined as the difference between the highest and lowest elevations of the runway centerline divided by the runway length. Therefore, increase the obtained runway lengths from the figures to account for (1) takeoff operations when the effective runway gradient is other than zero and (2) landing operations of turbojet-powered airplanes under wet and slippery runway surface conditions. These increases are not cumulative since the first length adjustment applies to takeoffs and the latter to landings. After both adjustments have been independently applied, the larger resulting runway length becomes the recommended runway length. The procedures for length adjustments are as follows:

a. Effective Runway Gradient (Takeoff Only). The runway lengths obtained from figures 3-1 or 3-2 are increased at the rate of 10 feet (3 meters) for each foot (0.3 meters) of elevation difference between the high and low points of the runway centerline.

b. Wet and Slippery Runways (Applicable Only to Landing Operations of Turbojet-Powered Airplanes). By regulation, the runway length for turbojet-powered airplanes obtained from the "60 percent useful load" curves are increased by 15 percent or up to 5,500 feet (1,676 meters), whichever is less. By regulation, the runway lengths for turbojet powered airplanes obtained from the "90 percent useful load" curves are also increased by 15 percent or up to 7,000 feet (2,133 meters), whichever is less. No adjustment is necessary by regulation for turboprop-powered airplanes.

305. PRECAUTION FOR AIRPORTS LOCATED AT HIGH ALTITUDES. At elevations above 5,000 feet (1,524 m) mean sea level, the recommended runway length for *propeller* driven airplanes of 12,500 pounds (5,670 kg) MTOW or less found in chapter 2 may be *greater* than those determined in this chapter for turbojet-powered airplanes. In this case, the longer recommended runway length of the small airplane weight category must be provided.

306. GENERAL AVIATION AIRPORTS. General aviation (GA) airports have witnessed an increase use of their primary runway by scheduled airline service and privately owned business jets. Over the years business jets have proved themselves to be a tremendous asset to corporations by satisfying their executive needs for flexibility in scheduling, speed, and privacy. In response to these types of needs, GA airports that receive regular usage by large airplanes over 12,500 pounds (5,670 kg) MTOW, in addition to business jets, should provide a runway length comparable to non-GA airports. That is, the extension of an existing runway can be justified at an existing GA airport that has a need to accommodate heavier airplanes on a frequent basis.

CHAPTER 4. RUNWAY LENGTHS FOR REGIONAL JETS AND THOSE AIRPLANES WITH A MAXIMUM CERTIFICATED TAKEOFF WEIGHT OF MORE THAN 60,000 POUNDS (27,200 KG)

401. DESIGN GUIDELINES. The design procedure for this weight category requires the following information: the critical design airplanes under evaluation and their APMs, the maximum certificated takeoff weight or takeoff operating weight for short-haul routes, maximum certificated landing weight, airport elevation above mean sea level, effective runway gradient, and the mean daily maximum temperature of the hottest month at the airport. Apply the procedures in this chapter to each APM to obtain separate takeoff and landing runway length requirements. Apply any takeoff and landing length adjustments, if necessary, to the resulting lengths.

402. DESIGN APPROACH. The recommended runway length obtained for this weight category of airplanes is based on using the performance charts published by airplane manufacturers, i.e., APMs, or by contacting the airplane manufacturer and/or air carriers for the information. Regardless of the approach taken by the airport designer, the design procedure described below must be applied to the information/performance charts. Both takeoff and landing runway length requirements must be determined with applicable length-adjustments in order to determine the recommended runway length. The longest of the takeoff and landing runway length requirements for the critical design airplanes under evaluation becomes the recommended runway length.

a. Airport Planning Manual (APM). Each airplane manufacturer's APM provides performance information on takeoff and landing runway length requirements for different airplane operating weights, airport elevations, flap settings, engine types, and other parameters. It is noted that airplane manufacturers do not present the data in a standard format. However, there is sufficient consistency in the presentation of the information that allows their application in determining the recommended runway length as described in paragraph 403.

b. United States Federal Aviation Regulations (FAR) and European Joint Aviation Regulations (JAR) or Certification Specifications (CS).

(1) Recently CS have replaced the European JARs that were previously issued by the Joint Aviation Authorities of Europe. Today the European Aviation Safety Agency (EASA) issues all CS**.**

(2) Airport designers and planners should be aware that some APM charts provide curves for both FAR and JAR (or CS) regulations. That is, a chart may contain dual curves labeled "FAR" and curves labeled "JAR." In the case for air carrier operators under the authority of the United States, the airport designer must use the curves labeled "FAR." In the case of foreign air carrier operators who receive approves by their respective foreign authority, such as EASA, the airport designer must use the curves authorized by the foreign authority, i.e., curves labeled "JAR," "CS", or "FAR." Therefore, the recommended labeled-curves that airport designers must use are those that the authorizing aviation authority approved for the air carrier's airplane fleet**.**

c. Airplane Manufacturer Website. Appendix 1 provides the website addresses of the various airplane manufacturers to assist in obtaining APMs or for further consultation.

403. PROCEDURES FOR DETERMINING RECOMMENDED RUNWAY LENGTH. Determine both takeoff and landing runway length requirements as prescribed below, select the longest resulting takeoff and landing runway lengths, then apply any length adjustments described in the following subparagraphs. The longest resulting runway length between the takeoff and landing runway lengths for the critical design airplanes under evaluation becomes the recommended runway length. Appendix 3 offers several examples that employ the design guidelines and procedures. *It is noted that the charts used in this procedure are provided by the airplane manufacturers for information only and not for flight operations. The pilot must use the FAA-approved flight manuals to conduct flight operations*.

a. The Temperature Parameter in APM Takeoff Charts. The parameter airport temperature is used only for takeoff length determinations by setting it equal to the "mean daily maximum temperature of the hottest month at the airport." In turn, APMs provide takeoff runway length data in terms of airport elevation and standard day temperatures (SDT). Figure 4-1 shows how APMs correlate SDTs with airport elevations. Fortunately many airplane manufacturers provide at least two takeoff runway length requirement charts, one at SDT (59° F (*15°*

C)) and one at SDT + some additional temperature, for example, SDT + 27° F (*SDT + 15°C*). The latter chart corresponds to 59° F + 27° F = 86° F (*15°C + 15°C = 30°C.*) Hence, the *potential benefit* for airport designers is quick and easy takeoff length determinations when the value of airport temperature, "mean daily maximum temperature of the hottest month at the airport," *equals or is less than* the provided SDT. In order to *augment this benefit*, it is acceptable for airport designers to use a SDT chart if it is no more than 3° F (1.7° C) lower than the recorded value for the "mean daily maximum temperature of the hottest month at the airport". For example, a SDT+ 27° F (*STD + 15°C*) chart could be used when airport temperatures are equal to or less than 89° F (3° F + 86° F) (*30°C [15°C + 15°C]*). If no SDT chart is available for the recorded airport temperature, consult the airplane manufacturer directly to obtain the takeoff length requirement under the same conditions outlined in this paragraph.

Table 4-1. Relationship Between Airport Elevation and Standard Day Temperature

Airport Elevation [1]		**Standard Day Temperature [1] (SDT)**	
Feet	Meters	° F	° C
0	0	59.0	15.00
2,000	609	51.9	11.04
4,000	1,219	44.7	7.06
6,000	1,828	37.6	3.11
8,000	2,438	30.5	-0.85

Note 1: Linear interpolations between airport elevations and between SDT values are permissible.

b. Landing Length Requirements. For the airplane model with, if provided, the corresponding engine type under evaluation:

(1) Locate the landing chart with the highest landing flap setting (if more than one flap setting is offer), zero wind, and zero effective runway gradient. If the chart does not indicate the wind or effective runway gradient conditions, assume they are equal to zero.

(2) Enter the horizontal weight axis with the operating landing weight equal to the maximum certificated landing weight. Linear interpolation along the weight axis is allowed. Do not exceed any indicated limitations on the chart.

(3) Proceed vertically to the airport elevation curve, sometimes labeled "pressure altitude." Interpolation between curves is allowed. It is noted that some charts simultaneously show both the *"dry runway"* and *"wet runway"* curves. Use the *"wet runway"* curve. Wet runway conditions are required only for turbojet-powered airplanes (see paragraph 508). See step (5) below for the turbo-jet powered airplanes when the chart only provides "*dry runway*" curves.

(4) Proceed horizontally from the wet runway curve to the length axis to read the runway length. Linear interpolation along the length axis is allowed.

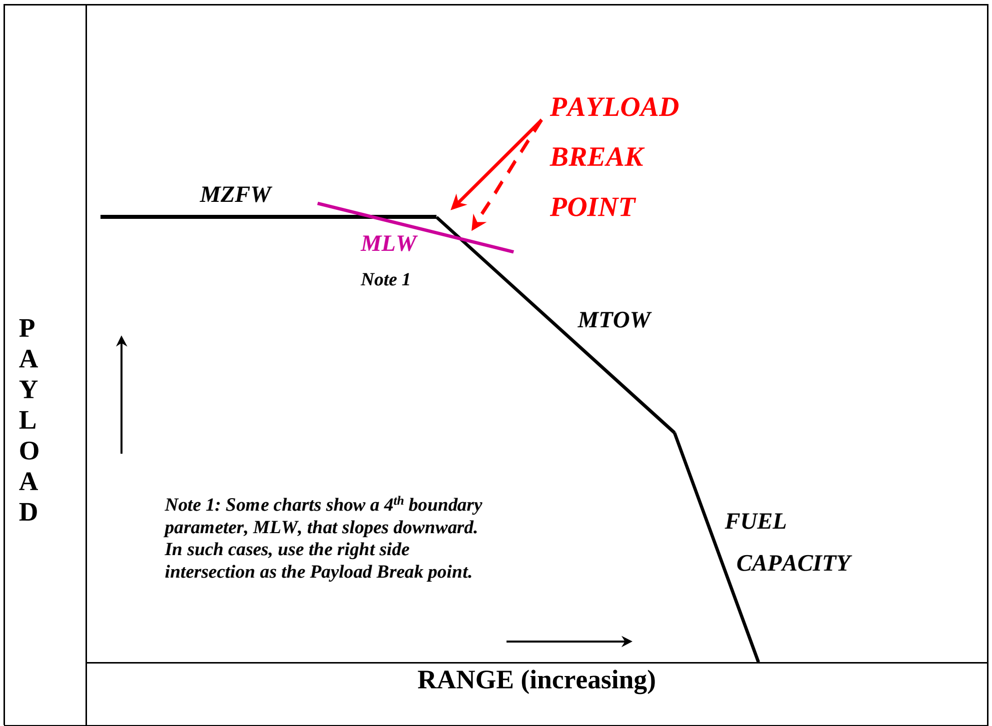
(5) Increase the obtained landing length for "dry runway" condition by 15 percent for those cases noted in paragraph 508. No landing length adjustment is necessary by regulation for non-zero effective runway gradients for any airplane type.

c. Takeoff Length Requirements. For the airplane model with, if provided, corresponding engine type under evaluation:

(1) Locate the takeoff chart with dry runway, zero wind, and zero effective runway gradient conditions for the appropriate SDT chart (within the temperature range for the airport's mean daily maximum temperature of the hottest month at the airport). If the chart does not indicate the "zero wind" or "zero effective runway gradient" conditions, assume they are equal to zero, but this is not a conservative assumption.

(2) Enter the horizontal weight axis with the operating takeoff weight equal to maximum certificated takeoff weight. For Federally funded projects, the airport designer must take into account the length of haul (range) that is flown by airplanes on a *substantial* use basis. The length of haul range will determine the operating takeoff weight for the design airplanes under evaluation. Long-haul routes should set the operating takeoff weight equal to the MTOW while short-haul routes should apply the actual operating takeoff weight. The Payload Break point as shown in figure 4-1 in conjunction with the *Payload-Range* charts provided by APMs for the design airplane(s), determine whether or not to use MTOW. Figure 4-1 illustrates a generic Payload-Range chart with Range and Payload axes, the Payload Break point, and the boundary parameters. For length of haul ranges that equal to or exceed the Payload Break point, the operating takeoff weight is set equal to the MTOW. For all the other cases, set the design operating takeoff weight equal to the actual operating takeoff weight. For the latter case, *AC 120-27D, Aircraft Weight and Balance Control*, provides average weight values for passengers and baggage for payload calculations for short-haul routes.

Figure 4-1 Generic Payload-Range Chart



MLW maximum design landing weight
MTOW maximum design takeoff weight (some APMs label it Brake Release)
MZFW maximum design zero fuel weight (some APMs label it Maximum Design Payload)

(3) Proceed vertically to the airport elevation curve without exceeding any indicated limitations, such as, maximum brake energy limit, tire speed limit, etc. Interpolation between curves is allowed because the chart is used for airport design as compare to flight operations. It is also noted that some airport elevations curves show various flap settings along the curve. In such cases, continue to use the same airport elevation curve.

(4) Proceed horizontally from the airport elevation curve to the runway length axis to read the takeoff runway length. Linear interpolation along the runway length axis is allowed.

(5) Adjust the obtained takeoff runway length for non-zero effective runway gradients (see paragraph 509). In those cases the airport designer must increase the obtained length by 10 feet (3 m) per foot (0.3m) of difference in runway centerline elevations between the high and low points of the runway centerline elevations.

d. Final Recommended Runway Length. The final recommended runway length is the longest resulting length after any adjustments for all the critical design airplanes that were under evaluation.

404. EXAMPLES. Appendix 3 provides example scenarios utilizing APM performance charts.

CHAPTER 5. DESIGN RATIONALE

501. INTRODUCTION. This chapter explains the application of eight factors that affect runway lengths. Previous chapters describe how to use performance curves and tables to determine the recommended runway length. However, the airport designer has the option to determine the recommended runway length by obtaining data provided in airplane flight manuals and then equally applying the eight variable factors discussed in this chapter and all other factors mentioned in the respective chapters. Table 5-1 summarizes the eight variable factors. For Federally funded projects the eight variable and other factors mentioned need to be applied in a manner to produce the shortest runway length.

502. AIRPLANES. The design criterion is to catalog the current or forecasted critical design airplane(s) that will use the runway and require the longest runway length.

503. LANDING FLAP SETTINGS. The design criterion is to select the landing flap setting that produces the shortest runway length. Figures in chapters 2 and 3 are based on this design criterion. Chapter 4, which relies on the use of an APM, directs the airport designer to select the flap setting that generates the shortest runway length from among the certificated landing flap settings.

504. AIRPLANE OPERATING WEIGHTS. The recommended runway length is based on expected airplane operating weights during takeoff and landing operations. The expected landing weight is the lower of the maximum allowable landing weights for the three conditions specified in subparagraph 504a and the takeoff weight is the lower of the maximum allowable takeoff weights for the seven conditions specified in subparagraph 504b.

a. Maximum Allowable Landing Weight. The airplane's maximum allowable landing weight is the lower of the following three conditions:

(1) Maximum structural landing weight.

(2) Climb limited landing weight.

(3) Runway length-limited landing weight (insufficient available runway length).

b. Maximum Allowable Takeoff Weight. The airplane's maximum allowable takeoff weight is the lower of the following:

(1) Maximum structural takeoff weight.

(2) Climb limited takeoff weight.

(3) Tire speed limited takeoff weight.

(4) Brake energy limited takeoff weight.

(5) Takeoff weight limited by maximum landing weight.

(6) Obstacle clearance limited takeoff weight.

(7) Runway length-limited takeoff weight (insufficient available runway length).

c. Operating Weights for Design. The design criterion is based on the following:

(1) Small Airplanes 12,500 pounds (5,670 kg) or less MTOW. Figures 2-1 and 2-2 along with the guidelines in chapter 2 provide recommended runway lengths by a single curve that incorporates both maximum allowable takeoff and landing weights.

(2) Large Airplanes over 12,500 pound (5,670 kg) MTOW.

i. Chapter 3. The curves of figures 3-1 and 3-2 provide runway lengths based on the percentage of fleet and percent of useful load. The curves used the lesser of the maximum allowable takeoff and landing weights as described above or the weight of the airplane with useful load.

ii. Chapter 4, Using Airplane Planning Manuals (APMs).

(a) For landing, use the maximum allowable landing weight excluding limitations of subparagraph 504a(3). In nearly all cases, the weight is set to the maximum structural landing weight.

(b) For takeoff, use maximum allowable takeoff weight, excluding limitations of subparagraph 504b(5), (6), and (7). For Federally funded projects, the airport designer must take into account the length of haul (range) that is flown by airplanes on a *substantial* use. In this case, use the determined length of haul (range) and compare it to the Payload Break point of the Payload-Range chart in the APM (see paragraph 403(c) for an explanation.) For ranges greater than or equal to the Payload Break point, set the operating takeoff weight equal to MTOW excluding limitations of subparagraph 504b(5), (6), and (7). For ranges less than the Payload Break point, use the calculated operating takeoff weight for the given range, i.e., short-haul routes. In many cases, the weight is set to the MTOW, thus resulting in a runway that permits airplanes to operate at full payload service capabilities.

505. AIRPORT ELEVATION. The design criterion is to substitute airport elevation above mean sea level for pressure altitude. This substitution is acceptable since the two are approximately equal and the probability of these conditions occurring simultaneously is relatively remote. Therefore, any difference would be slight.

506. TEMPERATURE. The design criterion is to use the mean daily maximum temperature of the hottest month at the airport. This temperature is readily available and yields a realistic operational length.

a. Application. Airport designers using chapters 2 and 3 are to apply the actual temperature value to the provided figures. Airport designers using an APM are to employ either the tables from the APM when the actual temperature falls within a prescribed temperature range or, when it falls outside the prescribed temperature range, to contact the airplane manufacturer directly for the applicable runway table.

b. Availability of Temperature Data. This information can be obtained from the publication "Monthly Station Normals of Temperature, Precipitation, and Heating and Cooling Degree-Days" (Climatography of the United States No.81). This is the official source for the mean maximum temperature for the hottest month. The latest data, averaged over a period of thirty years, may be obtained from the National Climatic Data Center, Federal Building, Asheville, North Carolina 28801. Phone: (828) 271-4800; fax: (828) 271-4876; or website: http://www.ncdc.noaa.gov/oa/ncdc.html (specify the state when ordering).

507. WIND. The design criterion is based on the condition of zero wind velocity for both takeoff and landing operations for all airplane weight categories. The figures in chapters 2 and 3 are based on zero wind conditions. Users of APMs are instructed to select the zero wind curves.

508. RUNWAY SURFACE CONDITIONS. The design criterion is to address wet, slippery runway surface conditions for only landing operations and only for turbojet-powered airplanes. The design criteria follows the 14 Code of Federal Regulations requirement that dry runway landing distances for turbojet-powered airplanes must be increased 15 % when landing on wet or slippery runways. Therefore, the obtained runway lengths from this AC for turbojet-powered airplanes are further increased by 15 percent. Many airplane manufacturers' APMs for turbojet-powered airplanes provide both dry runway and wet runway landing curves. If an APM provides only the dry runway condition, then increase the obtained dry runway length by 15 percent. The landing portion of the curves in figures 3-1 and 3-2 are based on dry runway conditions. Thus, as instructed by chapter 3, increase the landing dry lengths for turbojet-powered airplanes by 15 percent to increase the landing length, but not more than 5,500 feet (1,676 meters), whichever is less.

509. MAXIMUM DIFFERENCE OF RUNWAY CENTERLINE ELEVATION. The design criterion is to address uphill longitudinal runway profiles for takeoff operations of large airplanes. A runway whose centerline elevation varies between runway ends produces uphill and downhill conditions, which in turn, cause certain airplane weight categories to require longer operational lengths. This AC addresses the uphill condition, termed "*effective runway gradient,*" for *takeoff* operations by using the maximum difference of runway centerline elevation. For airplanes over 12,500 pounds (5,670 kg) maximum certified takeoff weight, the recommended runway length for takeoff derived from the curves of figures 3-1 and 3-2 or from the APMs must be increased by 10 feet per foot of difference in centerline elevations between the high and low points of the runway centerline elevations. Airport designers using APMs should also apply the same adjustment because APMs use zero effective runway gradients in their takeoff curves. This adjustment to the obtained runway length approximates the operational increase required to overcome the uphill effective runway gradient. For airplanes of 12,500 pounds (5,670 kg) or less MTOW, no operational requirement for an increase to the obtained runway length for takeoff is necessary to compensate for non-zero effective runway gradients. In the case for landing operations, no operational requirement for an increase to the obtained runway length for landing is necessary to compensate for non-zero effective runway gradients.

Table 5-1. Rationale Behind Recommendations for Calculating Recommended Runway Lengths

Variable Factors and Paragraph References		Family Groupings Consult Advisory Circular Figures 2-1 and 2-2	Family Groupings Consult Advisory Circular Figures 3-1	Family Groupings Consult Advisory Circular Figures 3-2	Airplane Performance Characteristics Non-Turbojet/Turbojet (Consult Airplane Manufacturer's Airport Planning Manuals (APM) Chapter 4)
Airplane Type (Paragraph 502)		Based on number of seats	Based on percent of fleet		Specific manual for each airplane

APPENDIX 3. EXAMPLES USING AIRPLANE PLANNING MANUALS

EXAMPLE SCENARIO #1. BOEING 737-900

1-1. INFORMATION. This example scenario, involving a Boeing 737-900, allows the airport designer to use published information in the airplane manufacturer's airport planning manual (APM). That is, the airport's mean daily maximum temperature for the hottest month falls within the permissible temperature range for the provided SDT + Temp chart. The airport designer will determine the separate length requirements for takeoff and landing, make necessary adjustments to those lengths, and then select the longest length as the recommended runway length. The example also assumes that the length of haul is of sufficient range so that the takeoff operating weight is set equal to the MTOW.

1-2. DATA. The calculation will use the following design conditions:

a.	Airplane	Boeing 737-900 (CFM56-7B27 Engines)
b.	Mean daily maximum temperature of hottest month at the airport	84° Fahrenheit (28.9° C)
c.	Airport elevation	1,000 feet
d.	Maximum design landing weight (see table A3-1-1)	146,300 pounds
e.	Maximum design takeoff weight (non-Federally funded project; see table A3-1-1)	174,200 pounds
f.	Maximum difference in runway centerline elevations	20 feet

1-3. CALCULATIONS. The steps used in the calculations are those provided in paragraph 403, noting applicable conditions. Figures A3-1-1 and A3-1-2 are used for the calculations. It is noted that the charts are only for airport design purposes and not for flight operations.

a. Landing Length Requirement (see figure A3-1-1).

(1) Step 1 – the Boeing 737-900 APM provides three landing charts for flap settings of 40-degrees, 30-degrees, and 15-degrees. The 40-degree flap setting landing chart, figure A3-1-1, is chosen since, it results in the shortest landing runway length requirement.

(2) Steps 2 and 3 – Enter the horizontal weight axis at 146,300 pounds and proceed vertically and interpolate between the airport elevations "wet" curves of sea level and 2,000 feet for the 1,000-foot wet value. Wet curves are selected because the airplane is a turbo-jet powered airplane (see paragraph 508). Interpolation is allowed for both design parameters.

(3) Step 4 – Proceed horizontally to the length axis to read 6,600 feet. Interpolation is allowed for this design parameter.

(4) Step 5 – Do not adjust the obtained length since the "Wet Runway" curve was used. See paragraph 508 if only "dry" curves are provide.

(5) The length requirement is 6,600 feet. **Note:** Round lengths of 30 feet and over to the next 100-foot interval. Thus, the landing length for design is 6,600 feet.

b. Takeoff Length Requirement (see figure A3-1-2).

(1) Step 1 – The Boeing 737-900 APM provides a takeoff chart at the standard day + 27°F (SDT + 15° C) temperature applicable to the various flap settings. Notice that this chart can be used for airports whose mean daily maximum temperature of the hottest month at the airport is equal to or less than 85.4° F (29.7° C). Since the given temperature for this example is 84° F (28.9° C) falls within this range, select this chart. See figure A3-1-2.

(2) Steps 2 and 3 – Enter the horizontal weight axis at 174,200 pounds and proceed vertically and interpolate between the airport elevation curves of sea level and 2,000 feet for the 1,000-foot value. Interpolation is allowed for both design parameters. **Note**: As observed in this example, a takeoff chart may contain under the “Notes” section the condition that linear interpolation between elevations is invalid. Because the application of the takeoff chart is for airport design and not for flight operations, interpolation is allowed.

(3) Step 4 – Proceed horizontally to the length axis to read 8,800 feet. Interpolation is allowed for this design parameter.

(4) Step 5 – Adjust for non-zero effective runway gradient (see paragraph 509).

$$8{,}800 + (20 \times 10) = 8{,}800 + 200 = 9{,}000 \text{ feet}$$

(5) The takeoff length requirement is 9,000 feet. **Note:** Round lengths of 30 feet and over to the next 100-foot interval. Thus, the takeoff length for design is 9,000 feet.

1-4. ANSWER.

Max. Landing Design Weight	146,300 pounds
Max. Takeoff Design Weight	174,200 pounds
Landing Length	6,600 feet
Takeoff Length	9,000 feet

Select the longest length for airport design. In this case, the takeoff length of 9,000 feet is the recommended runway length.

EXAMPLE SCENARIO #2. SAAB FAIRCHILD 340B

2-1. INFORMATION. This example scenario, involving a SAAB Fairchild 340B, allows the airport designer to use published information in the airplane manufacturer's airport planning manual (APM) instead of the figures provided in chapter 3 of this AC. The airport designer will determine the separate length requirements for takeoff and landing, make necessary adjustments to those lengths, and then select the longest length as the recommended runway length. The example also assumes that the length of haul is of sufficient range so that the takeoff operating weight is set equal to the MTOW.

2-2. DATA. The calculation will use the following design conditions:

a.	Airplane	Saab 340B (CT7-9B Engines)
b.	Mean daily maximum temperature of hottest month at the airport	74° Fahrenheit (23.3° C)
c.	Airport elevation	Sea level
d.	Maximum design landing weight (see table A3-2-1)	28,000 pounds
e.	Maximum design takeoff weight (non-Federally funded project; see table A3-2-1)	28,500 pounds
f.	Maximum difference in runway centerline elevation	20 feet

2-3. CALCULATIONS. The steps used in the calculations are those provided in paragraph 403, noting applicable conditions. Figures A3-2-1 and A3-2-2 are used for the calculations. It is noted that the charts are only for informational design purposes and not for flight operations.

a. Landing Length Requirement (see figure A3-2-1).

(1) Step 1 – the SAAB 340 APM provides two landing charts one for a flap setting of 25-degrees and one for a flap setting of 35-degrees. The 35-degree flap setting landing chart, figure A3-2-1, is chosen since it results in the shorter landing runway length requirement.

(2) Steps 2 and 3 – Enter the horizontal weight axis at 28,000 pounds and proceed vertically to the airport elevation curve for sea level. Select the dash curve labeled "FAR" and not the solid curve labeled "JAR" (see subparagraph 402b).

(3) Step 4 – Proceed horizontally to the length axis to read 3,450 feet.

(4) Step 5 – Do not adjust the obtained length for wet landing operations for the SAAB 340B since it is not a turbojet-powered airplane. The 15-percent adjustment applies only to turbojet-powered airplanes (see paragraph 508).

(5) The landing length requirement is 3,450 feet. **Note:** Round lengths of 30 feet and over to the next 100-foot interval. Thus, the landing length for design is 3,500 feet.

b. Takeoff Length Requirement (see figure A3-2-2).

(1) Step 1 – the SAAB 340 APM provides a takeoff chart at the standard day + 18°F (10° C) temperature for flap setting of 15-degrees. Notice that this chart can be used for airports whose mean daily maximum temperature of the hottest month at the airport is equal to or less than 80°F (26.7° C). Since the given temperature for this example is 74° F (23.3° C) falls within this range, select this chart. See figure A3-2-2.

(2) Steps 2 and 3 – Enter the horizontal weight axis at 28,500 pounds and proceed vertically to the airport elevation curve for sea level. Select the dash-curve labeled "FAR" and not the solid-curve labeled "JAR" (see subparagraph 402b). Interpolation is allowed for both design parameters.

(3) Step 4 – Proceed horizontally to the length axis, the result is 4,375 feet.

(4) Step 5 – Adjust for non-zero effective runway gradient (see paragraph 509).

$$4{,}375 + (20 \times 10) = 4{,}375 + 200 = 4{,}575 \text{ feet}$$

(5) The takeoff length requirement is 4,575 feet. **Note:** Round lengths of 30 feet and over to the next 100-foot interval. Thus, the takeoff length for design is 4,600 feet.

2-4. ANSWER.

Max. Landing Design Weight	28,000 pounds
Max. Takeoff Design Weight	28,500 pounds
Landing Length	3,500 feet
Takeoff Length	4,600 feet

Select the longest length for airport design. In this case, the takeoff length of 4,600 feet is the recommended runway length.

Ann Arbor Municipal Airport (ARB), Ann Arbor Michigan - Draft Environmental Assessment FAA Combined Comment Matrix

--May thru October 2016--

Comment Number	Page Number	Section Number	Paragraph	FAA Comment	MDOT Comment Resolution
1	1	title page	n/a	Need statement that "This Environmental Assessment becomes a *Federal* document…" before the FAA signature block, per FAA Order 1050.1F paragraph 6-2.1(a).	Revised draft EA
2	1	title page	n/a	Federal signature block should read "Responsible FAA Official"	Revised draft EA
3	9, 10 & 12	1.3 & 1.4	all	The Intro and background sections are discussing the State Standards. What are the Federal Requirements, in addition to the State reqmts? Critical Aircraft (1.5.1) & use of runway, Aircraft Activity (1.5.2) and Characteristics /Recommendations (1.5.3) all need to be in the background section before purpose and need section. Info in P & N needs to be in the background section.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The draft EA was revised to try and clarify the issue raised here, yet remain consistent with the example previously provided.
4	10	1.3	6	Need a discussion of the SBGP so that the reader is better able to understand the division of porposed actions between state and Federal	Revised draft EA
5	10	1.3	6	The paragraph is implying that the ALP is "fully approved".. If this were the case, it would have been unconditionally approved rather than conditionally approved. - Remove, "…it is in fact a fully approved ALP" - Add "conditional" to the last sentence, "...prior to AERO signing the conditional approval letter."	Revised draft EA
6	12	1.3	2	Please explain why the comments from the ADO were not addressed.	Revised draft EA
7	12	1.4	3	Is the purpose to meet the "FAA design objectives" or to accommodate the runway length needed by critical aircraft? This is implying that FAA is forcing the runway extension. Recommend changing the wording to clarify that aircraft are currently impacted by the shorter runway length. Is "increasing the line of sight for ATCT personnel" (presumably to improve a hotspot) more of a Need than a purpose?	Revised draft EA

8	12	1.4	4	States that the Need is to allow aircraft to operate at "Optimum Capabilities", should this include why there's a need to operate at "optimum capabilities"? Where are aircraft going, how often is the runway length affecting users?	In response to FAA's question regarding the need to allow the majority of critical aircraft to safely operate at their optimum capabilities without weight restrictions, we reference Paragraph 103 of FAA Advisory Circular 150/5325-4B, *Runway Length Requirements for Airport Design* . This paragraph states "The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions". The term "regularly use it" is further identified by the FAA as being the volume of usage provided by the runway's particular critical aircraft category (a minimum of 500 Annual Itinerant Operations). As far as FAA questions related to where the aircraft are going, an Origin-Destination Analysis was conducted using records obtained from the FlightAware Instrument Flight Rules (IFR) flight plan database associated with ARB. Flight operations were verified between ARB and at least 31 other states (approximately 63% of the continental U.S.). A list of all of the states involved is included in User Survey Supplemental Report No. 2, which is included in Appendix A-2 of the Draft EA. Additional information related to both of the above paragraphs is included in Sections 1.5.1, 1.5.2, and 1.5.3 of the Draft EA. Revised draft EA where appropriate.
9	12	1.4	3	Another sentence should be added after the first sentence of the paragraph to explain that the Purpose includes lengthening and shifting the runway. The second sentence is a Need and should be placed in the following paragraph.	Revised draft EA
10	12	1.4	all	Use of the term "Safely" implies the airport is not safe currently.	Revised draft EA
11	12	1.4	all	The purpose and needs statement should be complete and concise. This would include stating the problem that is looking to be addressed. A statement of overall safe and efficient and usable is a general statement and should be tightened up to reflect the discussion that follows. It is confusing on why the line of sight issue is singled out in the statement. Consider revising this statement.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The draft EA was revised to try and clarify the issue raised here, yet remain consistent with the example previously provided.
12	12	1.4	4	Clarify why the statement regarding aircraft says majority and not "all' aircraft?	Revised draft EA

13	13	1.5.1	2	Clarify whether the critical aircraft is properly grouped; is it okay to use the category B-II Small Aircraft? Cross reference B-II Large in the document.	The critical aircraft category of "B-II Small Aircraft" is properly grouped. In conducting the analysis of the critical aircraft, the distinction between Small versus Large category aircraft was considered in order to determine which Runway Length Curves in FAA Advisory Circular 150/5325-4B would be applicable to ARB. The curves in Chapter 2 are applicable to Small category aircraft, and the curves in Chapter 3 are applicable to Large category aircraft. The FAA recommended runway length of 4,200' was obtained from Figure 2-2 of Chapter 2. Had the critical aircraft at ARB been determined to be of the Large category, Tables 3-1 and 3-2 of Chapter 3 show that a much longer runway length would have been recommended by the FAA Advisory Circular. As far as FAA's request to cross reference the B-II Large category in the EA document, it is clearly referenced in section 1.5.3.
14	13	1.5.1	5	This paragraph is general in nature. A runway of 4,300 feet would allow without load restrictions… why 4,300's, why not 4,500, 5,000, or 10,000. The paragraph should instead define the runway length needs of the aircraft regularly using the runway, including haul lengths and loads rather than suddenly put out that 4,300 ft. would satisfy it.	As explained in Section 1.5.3, The FAA recommended runway length of 4,200 feet at ARB was obtained by calculation following the methodology referenced in Chapter 2 of FAA Advisory Circular 150/5325-4B, "Runway Length Requirements for Airport Design," a publication that is used nationally by the agency. The methodology and figures referenced in this section of the AC result in recommended runway lengths that are airport-specific, and they can vary by hundreds of feet from site to site, depending on the specific airport elevations and mean daily maximum temperatures used in the calculations. For example, if a representative higher-elevation airport in the Denver area had an elevation of 5,000 feet MSL, interpolation of Figure 2-2 of Chapter 2 of the AC shows that a runway length of approximately 5,000 feet in length would be recommended for the same B-II Small category of critical aircraft. In Michigan, airport elevations at our public-use airports only range from 578 feet to 1,622 feet MSL. The AERO runway length recommendation of 4,300 feet is a statewide standard for all airports in the state with category B-II critical aircraft classifications, as identified in Table 40 of the Michigan Airport System Plan (MASP). Since airport elevations and mean maximum temperatures do not vary significantly from airport to airport in Michigan, as opposed to many other states, AERO uses a single runway length recommendation for all airports of the same critical aircraft classification.
14 Cont.	13	1.5.1	5		The reason that the preferred alternative in the draft EA references a runway length of 4,300 feet is that this length meets both FAA and AERO runway length recommendations for critical aircraft in the B-II Small category.

15	13	1.5.1	6	The example seems to be an extreme case, how often does this user use the airport and what type of B-II aircraft is it? Why do they base at ARB instead of another close airport if they cannot use the aircraft to it's max capability above 40 degree F?	This user flies approximately 200 operations from ARB annually in Cessna 560 Excel jet. The user's business is based in Ann Arbor and the proximity to the airport provides convenience and a significant time savings over other local airports.
16	14	1.5.1	1	"Part 135 operators must reduce the useable length of the runway by anywhere from 20-35% based on runway conditions" has this quote been verified through citation to the actual Part 135?	The corporate pilot quotation regarding Part 135 operators has been verified to 14 CFR 135.385 paragraphs (b) and (f).
17	14	1.5.2	2	"Also, approximately 67% of the IFR flight plan records examined were between ARB and out-of-state locations." It's not clear how far of a distance these itinerant operations are going.. Are they all to surrounding States or are the haul length further?	The first sentence of Section 1.5.2 of the draft EA refers the reader to User Survey Supplemental Report No. 2 in Appendix A-2 for full details regarding the Origin-Destination Analysis. Exhibit No. 2 in the User Survey Supplemental Report lists the names of all 31 states (and Washington DC) that were associated with flights to and from ARB, as obtained from just the IFR Flight Plan database of FlightAware. Potentially, there are even more states associated with ARB flights than those confirmed by the referenced FlightAware records. Nonetheless, the records reviewed confirm that direct flights were conducted from ARB to other airports located in states as far away as Arizona, Texas, Florida, and Maine, just to name a few. The confirmation of flight operations between ARB and at least 31 other states verifies that operations are not confined to the few states surrounding Michigan, and that flights with long distance stage lengths are being conducted.
18	14	1.5.2	2	Second half of paragraph: Why are NetJets and AvFuel further called out in the two final sentences? What about the other six companies?	While many of the large corporations listed as users of ARB are commonly known, NetJets and AvFuel were lesser known entities that are active at the airport. NetJets because of the variety of businesses they serve and AvFuel because they are a local business.
19	16	1.5.3	FAA	Clarify why 4,200' (AC 150/5325-4B) would not support the Purpose and Need (P& N) as opposed to the requested 4,300.'	As explained in section 1.5.3 of the draft EA, utilization of current FAA runway design standards results in a recommended runway length of 4,200 feet at ARB. Utilization of current AERO runway design standards results in a recommended runway length of 4,300 feet. Although the recommendations are very similar, the reason that 4,300 feet was referenced in the draft EA in meeting the purpose and need is that it meets both the FAA and AERO current standards for runway length recommendations based on the critical aircraft category of aircraft.
20	16	1.5.3	FAA	Why isn't 4,200' listed as an alternative?	As explained in Comment 19 shown above, the reason that a runway length of 4,200 feet was not included as an alternative is that it is very similar in length to the 4,300 foot long alternative, and it does not meet current AERO runway design standards.
21	16	1.5.3	3	"The AERO recommendation of 4,300 feet is a statewide standard…" Recommend including how AERO developed their standard. What is this length based on, is it a random length they chose or does it meet the requirements identified in the P&N (optimum capabilities of the critical aircraft at ARB)?	Revised draft EA

22	16	1.5.3	4	Clarify whether the category B-II Small Aircraft requires a runway length of up to 4,300, or do the larger B-II airplanes require this length? The Small B-II may be on the lower end of the spectrum?	Revised draft EA
23	16/17	1.5.4	8 (last)/several	Clarify why User-Survey Reports were heavily relied upon? Why not TAF and Tower Counts? TAF was very close to accurate, however it is not logical to conclude (quantitative to qualitative) that ops will increase, because TAF may not always support constant increase. (Justify, e.g. is there a new coach that may boost attendance for Michigan games which will increase probability of increased attendance/travel?)	The reason that User Survey Reports were relied upon in this study is that they distinguish between the various aircraft makes and models, while the TAF and Tower Counts do not. From the various make and model information, aircraft approach categories, design groups, weight classifications (large vs. small), and critical aircraft categories can be determined. The TAF shows total numbers of forecasted operations, but no distinction of aircraft makes or models. The Tower Counts show historical numbers of total operations, but no distinction of aircraft makes or models. All three data sources (user surveys, TAF reports, and Tower Count reports) are useful for different aspects of analysis and forecasting, and all of these sources were used appropriately in this study. As stated in paragraph 1.5.4, the current TAF (which is prepared by FAA personnel and updated annually) forecasts continually increasing operations at ARB from year 2014 through year 2040, and the current MASP (which is prepared by MDOT personnel and updated periodically) also forecasts similar numbers of continually increasing operations through year 2030.
24	17	1.5.4	4	The paragraph indicates that the TAF is used to project forecasted operations to 2040. Does the airport have a locally developed forecast to compare this to? Does the airport understand how the TAF was developed and if it's really a good indicator of B-II itinerant ops?	While the airport does not have a locally developed forecast, the current FAA-developed TAF as well as the current MDOT-developed MASP both show continually increasing operations at ARB from present date at least through the year 2030. It is logical to conclude that all categories of aircraft that use the airport would show some increase in their annual operational numbers as part of the overall increase in activity. But even if category B-II operations remained at the level of the 538 annual operations that were documented in year 2014, and the entire increase in operations was attributed solely to increased activity by the smaller categories of aircraft (highly unlikely – especially if the runway is extended to 4,300 feet in length as proposed), the justification for the proposed project would still be substantiated both presently and through future years.
25	17	1.5.4	5	"…it is logical to conclude that operations by B-II category aircraft and larger will also increase beyond the 551 that were documented in 2014." Table 1-1 indicates that the 5-year trend from 2010 to 2014 is a steady or downward trend in B-II ops. Why is it logical to believe B-II ops will increase given the history of ops at the airport? - does the 551 include just B-II aircraft or B-II and larger as indicated in the paragraph? - How many of the 551 ops by B-II aircraft are by the representative King Air 200 or aircraft with 10 or more passenger seats?	Changes made and clarification added to Section 1.5.4 as requested. A table has also been added to User Survey Report No. 4 (Exhibit 1 of Appendix A-4 of the draft EA) which clarifies the number of annual operations conducted in 2014 by specific aircraft models and groupings (B-II, B-III, and C-III). As a result of preparing the table and analyzing and categorizing the operations by specific aircraft models, the operations performed exclusively by category B-II aircraft have been revised to 538 instead of the 551 that were mentioned in the previous draft of the EA. A total of 544 annual operations were performed by the combined B-II and Larger categories of aircraft. The text in Section 1.5.4 as well as numbers shown in Table 1-1 have been revised accordingly.

25 Cont.	17	1.5.4	5		In answer to FAA's question regarding a "steady or downward trend in B-II ops" from year 2010 to 2014: Table 1-1 of the draft EA does show minor fluctuations in the levels of estimated annual B-II operations during this time frame, from a low of 537 to a high of 600. These numbers were based on the minor fluctuations in total operations that occurred during the same time frame. The trend is not a steady downward trend as FAA suggests, but rather the numbers fluctuate both downwards and upwards. The numbers are also relatively close to each other, as opposed to being drastically different. The severe and multi-year economic recession that originated in 2009 likely played a role in the minor fluctuations of the total operations at ARB during the time frame in question, and as a result the minor fluctuations in the number of estimated B-II operations. Since the TAF (which is prepared by FAA personnel) shows that Total Annual Operations at ARB are forecasted to increase every year beyond year 2014, it is logical to conclude that operations by B-II category aircraft will also increase beyond the 538 that were documented in 2014. As noted in the text of revised Section 1.5.4 of the draft EA, even if B-II category operations do not increase in the future, but remain the same as in year 2014 (very unlikely if total operations are increasing), justification for the proposed runway extension would still be substantiated through the year 2040.
25 Cont.	17	1.5.4	5		In answer to FAA's questions regarding more details of operations performed by "B-II" versus "B-II and Larger" categories of aircraft, as well as more specifics regarding individual aircraft types, the information is shown in Exhibit 1 of User Survey Report No. 4 (see Appendix A-4 of the draft EA).
26	17	1.5.4	6	"These numbers have been calculated based on the percentage of actual B-II operations to actual Total Operations…" Why wasn't flight aware and FAA data used to determine actual usage by B-II aircraft over more years? Was FAA or Flight Aware data compared to the Airport User Survey data used for 2007, 2009, and 2014?	Changes made and clarification added to Section 1.5.4 as requested. In answer to FAA's questions, FlightAware data was used in the determination of B-II operations for survey data years 2007 and 2009, and FAA's Traffic Flow Management System Counts (TFMSC) data was used in the determination of B-II operations for survey data year 2014. This is clearly explained in User Survey Report Nos. 2, 3, and 4 (see Appendices A-2, A-3, and A-4 of the draft EA). Also, Exhibit 1 in each of these three reports shows a listing of the specific B-II category aircraft that were included in these records. Operational data obtained from both the FlightAware and the TFMSC sources is considered the most accurate available, as it is based on actual documented operations obtained from Flight Plans filed by pilots, over an entire calendar year of time. None of the data is based on estimates of annual operations generated by pilots, or proration of partial year survey data, as is common in conducting many other operational surveys.
27	20	1.6	first	First sentence should read: "The City of Ann Arbor proposes to extend and shift 160' the existing…"	Revised draft EA

28	20	1.6	2	"…as it does not currently meet the FAA design objectives" Recommend that all references to "FAA design objectives" be removed… the purpose should not be to meet FAA design objectives or put the onus on the FAA causing the runway length, but their user need for the longer runway	Excerpt directly from Purpose and Need...The **Purpose** of the proposed actions is to provide facilities at ARB that fully accommodate the operational requirements of critical aircraft currently using the airport, while at the same time enhancing safety. Revised draft EA as appropriate.
29	20	1.6	3	First sentence should read: "The existing runway approach light system pilots use to identify…"	Revised draft EA
30	20	1.6	3	After the second sentence, the remainder of the paragraph should read: "Due to difficulty in maintaing the system, the ODALS are currently temporarily out of service. Due to the fact that the Runway 24 end is proposed to be relocated, the FAA is proposing to permanenty decommission and remove the ODALS according to an FAA airspace letter signed on May 13, 2015, Airspace Case Number 15-AGL-14NR (Appendix H). A new runway approach lighting system will not be constructed as part of the proposed action."	Revised draft EA
31	20	1.6	4	Clarify throughout the document the direction of rw/taxi shifting and extension - either west or southwest	Revised draft EA where appropriate.
32	20	1.6	4	The Shift and Extension of the existing runway should be clarified, is the physical pavement going to be shifted and extended or is the pavement just going to be extended and the Runway 24 threshold moved 150 ft. If the remaining 150 ft pavement remains, is it usable? How will the existing taxiway across the threshold be handled (to the southeast)?	Revised draft EA to clarify, details contained in "proposed action" bulleted list.
33	20	1.6	5	delete entire paragraph, as this is not the appropriate section for this discussion.	Revised draft EA
34	20	1.6	6	Paragraph should read: "Implementation of the Preferred Alternative would meet the Purpose and Need by adequately addressing the needs of the…"	Revised draft EA
35	21	1.6	first bullet	To clarify the meaning, please reword this bullet	Revised draft EA
36	21	1.6	second bullet	specify that the parallel taxiway is designated Alpha	Revised draft EA
37	21	1.6	bullets 1, 2, 3	Clarify that 150' is being removed from the northeast end of the runway and added to the southwest end. Runway is being extended by 795'; please label the taxiway and rw; delineate why it is being extended by 945' if the new runway portion will be 795' once the 150' is newly constructed.	Revised draft EA (addressed by Comment #35)
38	21	1.6	bullets 1, 2, 3 & 4	Clarify whether entire runway is being reconstructed, or just portions to determine impacts.	There are no proposed actions to reconstruct the entire runway and the draft EA is clear that the proposed actions only impact the proposed 795' extension and the proposed 150' shift.
39	21	1.6	bullet 5	Reiterate throughout the document direction of the shift/extension	Revised draft EA where appropriate.
40	21	1.6	seventh bullet	Should read: "Relocate airport-owned Precision Approach…"	Revised draft EA
41	21	1.6	tenth bullet	Should read: "Relocate/reconstruct FAA-owned Ruwnay 6 Runway End Identifier…"	Revised draft EA
42	22	1.7.1	after first bullet	add new second bullet: "FAA acceptance of relocated NAVAIDs (REIL)	Revised draft EA

43	22	1.7.1	third bullet	I was unaware that this project would use AIP funds. If this is not the case, reword with the correct funding source or delete	In a December 2013 email between the FAA-Region and MDOT-AERO, the funding sources intended for the project were clarified and remain the same, State Apportionment, Non-primary Entitlements and State/Local Shares will be used.
44	22	1.7.1	3	This bullet needs to be removed. There are no AIP funds being sought or provided for this proposed action.	State Apportionment and Non-primary Entitlements are AIP funds.
45	22	1.8	all	The section labeled, "Other considerations" should be included in the purpose and needs section. These issues kept separate from the statement objectives makes it difficult to have a clear purpose and need statement and to recognize these as part of the project.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The draft EA was revised to try and clarify the issue raised here, yet remain consistent with the example previously provided.
46	22	1.8.1	1	"The proposed shift would enahance operatinal safety, and possibly prevent a runway incursion, by expanding the view of the hold area and paralle taxiway to ATCT personnel." Therefore, please clarify, does this this shift cause other operational issues with the existing Northeasternmost hangar apron view still blocked from ATCT line of sight? How will aircraft taxi to the Southeast hangar section? - Is 150 ft enough of a shift to remove the hot spot?	With the proposed shift of the A1 connector from Alpha Taxiway to Runway 06/24 to the southwest, the Line of Sight issue will be significantly improved. Aircraft entering the Movement Area from Echo, Delta and Charlie (east facing hangars only) will still have limited visual oversight by controllers. This will be a significant improvement over current conditions where all aircraft using the taxiway hold area of Runway 24 are in a restricted visibility area. The existing Delta taxiway from the southeast hangars will be shifted to the southwest as well under the proposed project. This will allow them full access from Runway 06/24 to the southeast hangar area with full visual access from the control tower. The proposed 150' shift will significantly improve the safety of ground operations of taxiing aircraft. While some visual restrictions for aircraft originating from the northeastern most T hangars will remain, it will be up the FAA to determine if this area should still be designated as a "hot spot."
47	23	1.8.1	second on page	In response to the first sentence, clarify what type of "more negative impacts" would there be?	Revised draft EA
48	23	1.8.1	2	"…than with the runway theshold shift alternative"… is the preferred alternative to shift the threshold only and leave the pavement, or to shift and remove the 150 ft of pavement?	Revised draft EA to clarify, details contained in "proposed action" bulleted list. (Section 1.6)
49	23	1.8.1	3	"…raising the tower in its existing location would very likely result in the tower penetrating the 7:1 transitional surfaces…" Has an airspace study been completed to determine if this is a hazard?	Changes made and clarification added to Section 1.8.1. In answer to FAA's question, yes an airspace study was completed to determine if a raised tower would become a hazard. See revised Section 1.8.1 for details.
50	23	1.8.1	4	How old is the ATCT? Is it due for a modernization or rehab that might cause it to be beneficial to move it?	The ATCT was constructed in the mid-1970's and the attached office structure was constructed around 2003. The ATCT exterior was rehabbed within the last 5 years. The Airport is unaware of any pending plans for additional modernization or rehab.
51	23	1.8.1	4	Delete "disruption of Airport Traffic Control operations"	Revised draft EA
52	23	1.8.2	1	"The proposed shift of the Runway 24 threshold would also allow for a clear 34:1 approach slope…" Why are they protecting for a 34:1 approach slope when the minimums for existing approaches are 1 mile? 34:1 is typically required for minimums below 3/4 mile. If the 34:1 doesn't apply, why would this be a "concern"?	The 34:1 approach slope is planned for future developments at ARB on the current ALP. (Sheet 4 - "Airport Layout Plan (Future)") Plus, any lowering of obstacles in the approach to a runway is an improvement and should always be attempted to improve the safety of the flying public.

53	23	1.8.2	5	Justify the slope gradient based on page 2 of the AC 150/5325 (10) Effective Runway Gradient	The justification of the slope gradient based on page 2 of the AC 150/5325 (10) Effective Runway Gradient will be accomplished once detailed design is performed on the preferred alternative.
54	24	1.8.3	1	Regarding 150/5235 4-B, Figures AC 2-1 and 2-2, an engineer from ARPs stated that the charts support the runway being extended to 4,150 when the temperature is higher than 82.5◦. But if the sponsor believes the longer runway is necessary please justify.	The mean daily maximum temperature of the hottest month of the year at ARB is 83.0 degrees F (July). The airport elevation is 839' MSL. When these numbers are factored into Figure 2-2 of FAA AC 150/5325-4B, the resulting recommended runway length is 4,200'. See the draft EA for additional information regarding the FAA recommendation of 4,200' versus the MDOT recommendation of 4,300'. (Section 1.5.3)
55	24	1.8.3	3	Please explain what is meant by a "local objective"	A "local objective" is a goal set by Ann Arbor Municipal Airport leadership that would be obtained by the implementation of the proposed airfield improvements.
56	24	1.8.3	3	several comments. How many overruns occurred? This objective should not be labeled as a local. The runway design criteria accounts for RSAs an RPZ for the critical aircraft.	Eleven overruns have been documented. If additional overruns occurred, the Airport has been unable to find verifiable documentation for them. As overruns are not officially recognized by the FAA or AERO as justification for extending a runway, the objective of keeping aircraft on the pavement is a local one. While the existing RSA and RPZ meet the design criteria for critical aircraft, the Airport believes that keeping aircraft on pavement instead of transitioning to an RSA or RPZ reduces the hazard to aircraft, their occupants and the airport facilities.
57	24	1.8.4	1	This section is being viewed as part of the justification for the statement. Commerce can not be of the P/N. Otherwise, other commerce alternatives will have to be included. Suggest that this section be removed.	On April, 21 2015 the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft. AERO put significant effort into modeling this draft after the Bolingbrook example and believes the content is consistent. The items included as "Other Considerations" are not items to justify the proposed project but are other items that will be impacted if the proposed project is constructed. These items are of significant interest or impact that they warrant explanation.
58	25	1.9	third bullet	How would the project "enhance operational safety in low-visibility conditions" without installing an ILS? Would providing a 34:1 approach really be enough to make this claim?	In answer to FAA's question, the project would enhance operational safety in low visibility conditions by providing a greater margin of safety between the approaching aircraft and the obstacles on the ground in the Runway 24 approach area. Since the 34:1 approach surface provided by the proposed project is flatter than the existing 20:1 approach surface, obstacles with heights just below the 34:1 surface would be farther away (vertically) from overflying aircraft than obstacles with heights just below the 20:1 surface. The greater vertical distance of object-free airspace would obviously increase the margin of safety in low visibility conditions.
59	25	1.9	last bullet	explain "local objective"	(Addressed by Comment #55)
60	25	1.9	all	The summary should be moved up and be made part of the P/N statement and renamed objectives. The document to this point uses safely through out. Either remove the language or change to enhanced safety.	MDOT-Aero and the FAA-Region have had previous discussion regarding the summary, the summary will be left in place. Revised draft EA to address safely/enhanced safety where appropriate.

61	26	2	1	include the number of alternatives at the beginning of the sentence. Drop the rest of the sentence after "project"	Revised draft EA
62	26	2.1.1	3	In regards to the second and third sentences of the paragraph: Does the fact that B-II aircraft still land at ARB instead of nearby YIP demonstrate that the restrictions put on those aircraft by the short runway are not significant, otherwise these users would land at YIP instead? For clarity, this should be rebutted in order to strengthen the Purpose and Need	The Ann Arbor Municipal Airport cannot dictate which airfield a pilot uses. Many factors go into that aircraft operator's decision on where to operate from. B-II aircraft are a regular user of the Airport and the existing runway configuration does not satisfy the FAA design objective of providing sufficient runway length to allow airplanes that regularly use it to operate without weight restrictions. The proposed project would also result in ARB achieving full compliance with all AERO basic development standards outlined in the MASP 2008 for category B-II airports.
63	26-28	2.1	all	What were the criteria used to dismiss these alternatives. For example, there is no mention of environmental impacts etc. in the purpose and needs statement	As is consistent with the standard EA process, alternatives are most commonly dismissed because they failed to meet the Purpose and Need or other alternatives had less harmful impacts on the environment.
64	28	2.2	1	how were these alternatives deemed feasible?	As is consistent with the standard EA process, alternatives are typically only carried forward if they meet the Purpose and Need and avoid, minimize, and/or appropriately mitigate impacts on the environment.
65	29	2.2	3	Build Alt 3 - label the parallel taxiway that will be extended; will a portion of the taxiway or all be demolished and reconstructed? Or new construction to southwest?	Existing taxiway connector Alpha1 will be demolished on the northeast end of the runway and reconstructed 150' to the southwest. The parallel taxiway will be extended with new construction to the southwest. Revised draft EA.
66	33	Figure 3.4	map	For clarity please label the taxiway and runway and the lengths, on the same map	Revised draft EA
67	34	2.3.1	2	The airport is currently safe. This section implies the airport is unsafe.	Revised draft EA
68	35	2.3.3	1	Line of sight is not listed as an objective. Need to make sure the P/N statement is concise, clearly stated, focus, with justification and objectives. Please provide better clarity/flow when tracking the P/N section.	Line of Sight is shown as a "Need" in the revised Purpose & Need section and is consistently addressed in each of the alternative evaluations.
69	35	2.4	1	Clarify that the preferred ALT 3 is to remove 150' from the east end of the runway, (adding back 150' on the west end) plus the adding the 795' and shifting to the southwest	Revised draft EA
70	35	2.4	2	Add on to end of first sentence: "except for the ODALS."	Revised draft EA
71	35	2.4	2	Third sentence should read: "FAA approval for the relocation of the REILS will be required as part of the proposed action."	Revised draft EA
72	35	2.4	2	Fifth sentence should read: "If the decommissioning proposal is finalized, the approach lighting system will be removed and no relocation will occur."	Revised draft EA

73	36-68	3	all	This section needs to use the environmental impact categories specified in FAA Order 1050.1F, paragraph 4-1	The draft EA has been in process continually since 2009 and significant effort has gone into preparing it in accordance with FAA Orders 1050.1E and 5050.4B. Also, as previously mentioned in this comment matrix the FAA-Region provided a 2011 Environmental Assessment from Bolingbrook's Clow International Airport, as an example for MDOT-AERO to follow while re-organizing and revising this draft, it was also prepared in accordance with 1050.1E. Because this change would result in no change to content and the regulatory agencies, tribes and public have previously reviewed the draft EA as is, MDOT-AERO proposes to leave the draft EA unchanged.
74	36	3.1	1	What about the other noise impacts, such as from construction activities?	Noise associated with construction activities is covered in Construction Impacts category not the Noise category. (Section 3.15) Revised draft EA to clarify.
75	36	3.1	all	What about evaluation of the no action alternative for noise impacts?	Included in Section 3.1.2
76	36	3.1.1	1	The title of the methodologies need to be included in the paragraph	They are described in the same section.
77	37	3.1.1	last four bullets on page	Update these sources with more recent versions	These are the original sources used for the 2009 Noise Impact Analysis and should remain for consistency. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
78	39	3.1.3	all	Why not just redo the noise analysis with 2015 data?	The effort, timing and cost associated with redoing the noise analysis does not seem prudent, especially for little anticipated change in fleet mix and night operations, and a forecasted decrease in annual operations from the level analyzed in the original 2009 noise analysis. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
79	41	4.1	map	Noise Contour - Existing Conditions, please clarify the year.	Revised draft EA
80	42	4.2	map	No build - are the existing conditions still the same? Reasonable representation?	Revised draft EA. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
81	43	4.3	map	Preferred Alternative - Please delineate the projection out for the next five years	Revised draft EA. MDOT-Aero reevaluated the 2009 study in 2015 and found it to be substantially valid. (Section 3.1.3)
82	46	Figure 4.4		Is a newer source available than June 2011?	No
83	49	Figure 4.7		Is a newer source available than June 2011?	No
84	50	3.3.2	4	Update U.S. Census data with more recent source	Revised draft EA
85	51	3.3.2	1	Update U.S. Census data with more recent source	Revised draft EA
86	51	3.3.2	2	Update U.S. Census data with more recent source	Revised draft EA
87	52	3.3.4	4	Update U.S. Census data with more recent source	Revised draft EA
88	53	Table 3-2		Update U.S. Census data with more recent source	Revised draft EA

89	55	3.4	1	According to the Federal Register EPA 40 CFR Part 81 which was published in January of 2015, using the latest information from 2012 Annual Fine Particulate Matter NAAQS, Washtenaw (Livingston, Macomb etc.) County; PM 2.5 is Unclassified attainment. Clarify that the data submitted is correct.	The following is an excerpt directly from the 2014 Michigan Annual Air Quality Report published in June 2015 - All Michigan counties from 2010-2014 met the 1997 annual PM2.5 standard of 15 µg/m3 and the 2006 24-hour PM2.5 standard of 35 µg/m3. The EPA designated Michigan in attainment of these standards in August 2013. In December 2012, the EPA revised the annual primary standard to12 µg/m3 while the annual secondary standard remained at 15 µg/m3. The primary and secondary 24-hour standard remained as 35 µg/m3. The EPA has not made designations for the 2012 NAAQS revisions; however, PM2.5 concentrations are below 12 µg/m3 throughout Michigan. (DEQ 2016 Attainment Map Appendix C)
90	55	3.4	3	In regard to air quality, please provide the data from MDEQ (Do not see in Appendix D - there is a Land and Water Management and Wetlands letter)	Appendix D is specifically for "Early Agency Coordination" documentation, Appendix H is for "Additional Agency Correspondence" and includes the letter from MDEQ to EPA.
91	55	3.4	4 thru 7	The discussion does not quite fit affected environment. In terms of air quality what is the baseline conditions.	This language was not included in the first draft EA, however during discussions with the FAA-Region during review of this draft EA, this language was specifically recommended and later provided by the FAA-Region for inclusion into this draft.
92	56	3.4	3	Is there are more recent study than the L&B study from 1996?	No
93	56	3.4	3	Fourth sentence: which standards is this referring to?	NAAQS as referenced in the following sentence.
94	56	3.4	3	Last sentence: The reference to "proposed projects at general aviation airports" is very broad. How could the report know the extent of future projects at all GA airports in MI, especially if the report in 20 years old?	It is assumed that the report considered past GA airport projects and their typical scope and impacts when referencing proposed projects and made the general assertion that those projects are typically not of the scale to contribute to any NAAQS exceedances.
95	56	3.4	4	Please reword paragraph, as it is very confusing	Revised draft EA
96	56	3.4	4	It is not clear if this area is in a nonattainment area or maintenance area. Also not how this estimate was achieved. What calculations, models and sources were used. The citing of the court case should be removed and CAA regulations should be cited.	Based on the 2014 Annual Air Quality Report all of Michigan is in attainment. The following is an excerpt directly from the 2014 Michigan Annual Air Quality Report published in June 2015 - "Michigan ambient NO2 levels have always been well below the NAAQS. Since March 3, 1978, all areas in Michigan have been in attainment for the annual NO2 NAAQS...all monitoring sites have had an annual NO2 concentration at less than half of the 0.053 ppm NAAQS. As such, the DEQ requested a designation of unclassifiable/attainment for the entire state. Unclassifiable/attainment means that there are no air quality measurements that would justify classifying these attainment areas as either serious or moderate nonattainment areas." (DEQ 2016 Attainment Map Appendix C)
97	56	3.4	5	First sentence referenres NOX - what about the other NAAQS?	Revised draft EA.
98	56	3.4	5	Last sentence: replace "should" with "would"	Revised draft EA
99	57	3.5	1	How was it determined that the water quality is degraded. Was MDEQ contacted? With out some reliable way of establishing this the baseline for environmental conditions is not met.	There was no formal determination that it is degraded, only as it states, that it is "likely degraded", based on the existing conditions, observations and characteristics provided. Given that this is primarily a storm water dominated system, as described, it doesn't seem unreasonable to conclude that it is likely degraded, as it is common thought that many storm water dominated systems are.

100	57	3.5.1	4	Please clarify the status of the NPDES permit, as mentioned in secton 4.2.2? The reason for the permit should also be stated.	There are two distinctly different NPDES Storm Water Discharge Permits at ARB, one permanent for municipal storm water discharges and the other temporary for storm water discharges associated with construction activity. Revised draft EA to clarify.
101	57	3.5.2	2	Did not find a map that shows the 14 soil units and how their location to the proposed action site	Revised draft EA
102	58	3.5.2	1	Did not find a map that shows the wellhead area in relationship to the proposed action site.	A map of the City of Ann Arbor's Wellhead Protection Areas is now included. (Appendix H) The airport is located within the Steere Farm Wellhead Protection Area.
103	58	3.5.2	4	What about soils? The paragraph also mentions a new water line. Please provide more info on the water line.	The City replaced an existing raw (untreated) water line with a new 30" raw water line in 2010 along the east side of the airport. (Appendix H)
104	61	3.7	1	What were the results of the survey?	Revised draft EA
105	61	3.7	3	Did SHPO/THPO provide concurrence? If so, please state so.	Yes. Revised draft EA
106	61	3.8	2	Fourth sentence: be more location-specific, as the way the sentence is worded makes it sound the grassy meadows are within the RSA.	Revised draft EA
107	61	3.8	2	Last sentence: This discussion should be expanded. What does the agreement call for? Why does it exist?	This discussion is already included in Section 3.9 Threatened & Endangered Species and Section 4.2 Mitigation Measures.
108	62	3.8	4	Third sentence: What does the Audubon society think of this? Were they contacted as part of the EA public outreach process?	Revised draft EA
109	63	3.9	1	Update June 2009 survey, as this is already seven years old.	Revised draft EA
110	63	3.9	3	Last sentence: Did Audubon agree with this as well?	Revised draft EA
111	63	3.9	3	Update letters from 2009 for preferred alternative (Department of Natural Resources have instructions that may have changed)	As soon as this draft EA is finalized, the regulatory agencies will be contacted in writing and given the opportunity to review, comment and/or update their instructions.
112	63	3.1O	1	Update June 2009 survey. As part of the wetlands analysis, was USACE contacted? If so, did they make a jurisdictional determination? Are there any wetlands on the Rwy 06 approach, as the USFWS map depicts a wetland area. What about the removal of the ODALS - will this action impact the wetlands?	Review of available data sources was completed in 2015 and appear largely consistent with what was found in 2009. MDOT-AERO will complete a real-time field review of project areas to confirm the presence of wetlands, or lack thereof, during project design to ensure proper permitting requirements are met, if necessary. In Michigan, the USACE only retains authority over certain wetlands, the USEPA has agreed that MDEQ has compliance responsibilities over all the rest. Both MDOT-AERO and MDEQ have concluded that the wetlands at ARB are not regulated by USACE.
113	64	3.11	3 and 4	Was the floodplain analysis and conclusion confirmed with the local Floodplain Administrator?	The floodplain impacts were discussed at a meeting of MDOT Statewide Environmental Permit Coordinators and Resource Specialists. This level of analysis is adequate for draft EA purposes and the regulatory agency will be involved, as necessary, prior to the project being finalized.
114	64	3.11	3	Agencies should be changed to Agency. A flood plain map that shows the flood plain and the floodway with the proposed action should be included to support the discussion.	Revised draft EA (Appendix H)

115	64	3.12	1	See US Department of Agriculture NRSC letter, dated September 3, 2009, signed by Steve Olds. Update needed since this Agency requested follow up. See Appendix D-7	The following is an excerpt directly from the September 2009 NRCS Letter - "Some prime and farmland of local importance would be impacted by the project. If the project proceeds, I would urge you to utilize NRCS standards and specifications for conservation practices..." The draft EA is still in process and cannot proceed until that process is completed. Revised draft EA to clarify. As soon as this draft EA is finalized, the regulatory agencies will be contacted in writing and given the opportunity to review, comment and/or update their instructions.
116	66	3.14	1	Last sentence: delete "within the light lane"	Revised draft EA
117	66	3.14	2	Second sentence: Wouldn't these impacts be noted here? Where else would they be noted?	Revised draft EA
118	67	3.17		Why is this a separate section, as it is not an impact category?	Hazardous Waste Sites are an impact category under 1050.1E. (Addressed by Comment No. 73.)
119	67	3.18	1	Change to ASTM International Standard 1527-13	Revised draft EA
120	68	3.18	2	Last sentence: Add that any contamination encountered would be characterized and handled in accordance with state regulations	This language is already included later in the "Consequences of the Preferred Alternative" paragraph of Section 3.18 as appropriate.
121	69	4		The title of this section sounds like Section 3. What is the purpose of this section? Recommend changing the title to mitigation.	Revised draft EA
122	69	4	-	Title should be changed to Mitigation. EC was included in the previous section	Revised draft EA
123	-	-	-	In regard to the comment concerning Wildlife Hazards. The existence of the various nature features and species of concern should be assessed and part of the EA. FAA does not agree with the position that changing the profile of the airport will not change the relationship to the wildlife and their use of attractants. Only a certified Airport Wildlife Biologist is qualified to make that determination. The response to previous comment did not cite the participation of a certified Airport Wildlife Biologist.	This comment was not included in the revised draft EA, however it was included in the Response to Comments (Appendix K) . MDOT-AERO did consult with a certified Airport Wildlife Biologist from USDA when preparing the Response to Comments.
124	69	4.2.1	1	Last sentence: Does Audubon agree with this?	Revised draft EA
125	70	4.2.2	1	What about BMPs for air and water quality?	Addressed in Consequences of Preferred Alternative Sections of their respective impact categories.
126	71	5	1	The last public meeting was held six years ago; a new meeting will be needed.	This language is already included later in Section 5.2.2 Public Hearing.
127	71	5.1	1	What were the agencies' comments, at least in summary? What was MDOT's response?	Agency comments are provided in Appendix D and MDOT Responses are provided in Appendix K.
128	71	5.1	3	What did the local tribes say? Provide a summary.	Agency comments are provided in Appendix D and MDOT Responses are provided in Appendix K.
129	72	5.2.2	4	Add that another public meeting will be held.	This language was already included in the last paragraph of Section 5.2.2. Revised draft EA to clarify.

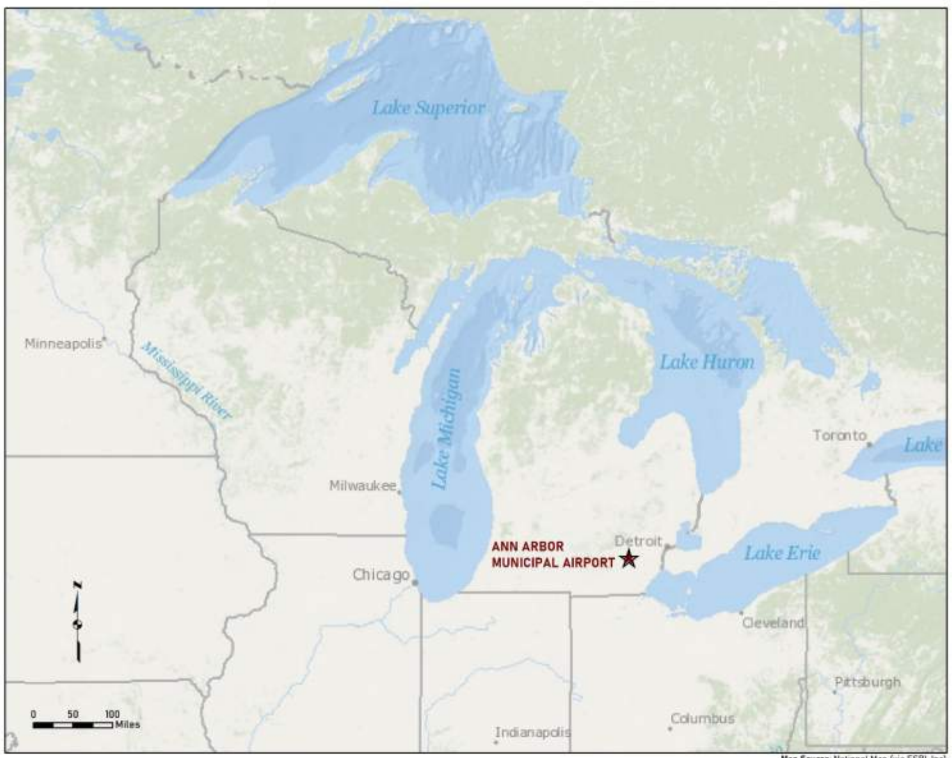
Chapter 1.0 Purpose and Need - DRAFT

Commented [LS(1]: This is a public document; therefore, please add graphics, photos, call-out boxes to describe/show/illustrate technical terms or equipment on an airport to ensure that this is readable and understandable for the general reader.

1.1 Introduction

The Ann Arbor Municipal Airport (ARB or Airport) is a public-use, general aviation airport owned and operated by the City of Ann Arbor. The Airport is within Pittsfield Charter Township, Washtenaw County, in southeastern Michigan (**Figure 1.0 Location Map**). Locally, ARB is approximately four miles south of downtown Ann Arbor, approximately 40 miles west of Detroit, and 10 miles west of Ypsilanti (**Figure 1.1 Vicinity Map**).

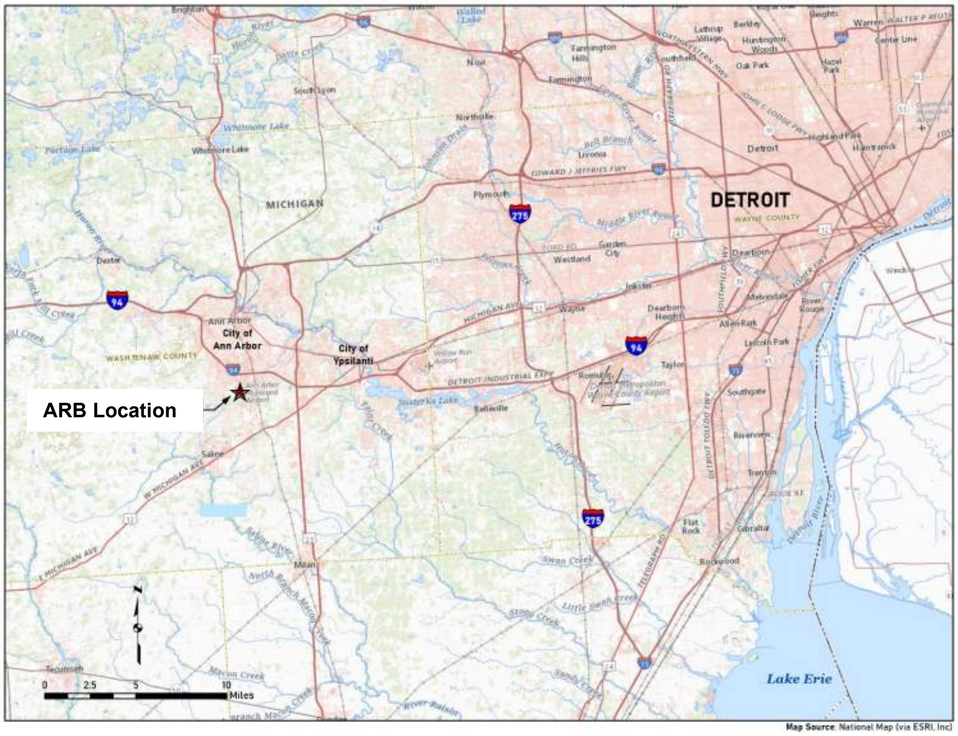
Figure 1.0 Location Map



Source: Mead & Hunt, 2020

Ann Arbor and the surrounding area is home to many prominent businesses and institutions with the University of Michigan being the area's largest employer. Manufacturing, health care, automotive, information technology, and biomedical research companies account for major employers in the region.

Figure 1.1 Vicinity Map



Source: Mead & Hunt, 2020

With many technological-driven industries, there is often a need for air transportation to bring workers, clients, suppliers, customers, and time sensitive parts/supplies to and from the region. These businesses operate a combination of turboprop driven and business jet aircraft. ARB is a vital transportation link and an economic driver for the community.

The Airport is also included in the Federal Aviation Administration (FAA) National Plan of Integrated Airport Systems (NPIAS). This designation is indicative of its significance in the national air transportation system. At the state level, the Michigan Department of Transportation Office of Aeronautics (MDOT AERO) classifies the Airport as a Tier-I, general aviation airport. Tier-I airports represent essential and critical state airport system goals and according to MDOT AERO should be developed to their full and appropriate extent[1].

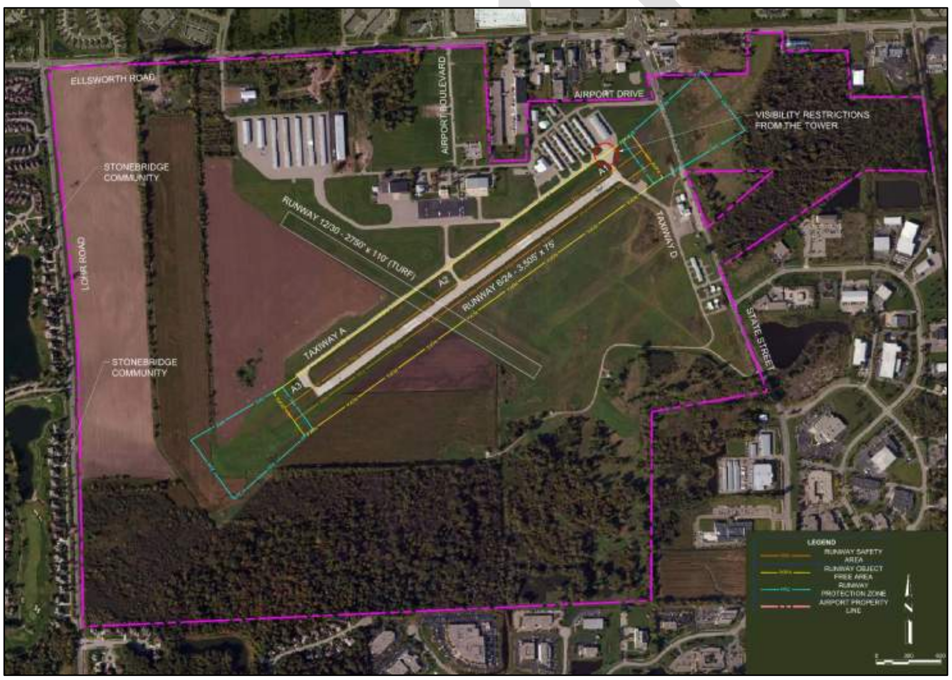
The Airport's primary runway, Runway 6/24, is paved and has a length of 3,505 feet with a width of 75 feet and is oriented in a northeast/southwest direction. ARB also has a turf runway, Runway 12/30, that is 2,750 feet in length and 110 feet in width and is oriented in a northwest/southeast direction. Runway 12/30 is used

1 2017 Michigan Aviation System Plan, Michigan Department of Transportation Office of Aeronautics, Page 2-9.

when weather permits and is not utilized by jet aircraft. Taxiway A parallels Runway 6/24 and has connector taxiways A1, A2, and A3 that provide access between the runway and the parallel taxiway. Several other connectors provide access between the parallel taxiway and the main apron with numerous hangars located on the airfield. **Figure 1.2 Existing Airfield Configuration** illustrates the airfield configuration and property boundary of ARB.

Runway 6/24 is equipped with Medium Intensity Runway Lighting (MIRL). The approach end of Runway 6 is equipped with a 4-light precision approach path indicator (PAPI), while the approach end of Runway 24 is equipped with a 2-box visual approach slope indicator (VASI). Both navigational aids are owned by ARB and assist aircraft with vertical guidance when landing. ARB is also served by an airport traffic control tower (ATCT) that manages the landing and departure of aircraft.

Figure 1.2 Existing Airfield Configuration



Source: Mead & Hunt, 2020

In addition to the ARB owned navigational aids described above, Runway End Identifier Lights (REIL) are also located at the approach end of Runway 6 but are owned by the FAA. Until recently, the approach to Runway 24 was equipped with FAA owned Omnidirectional Approach Lighting System (ODALS); however, they were decommissioned and removed in the summer of 2020. For additional maps and information on the Airport including its history, existing facilities, and the role it plays in the community and the region, see **Chapter 3.0 Affected Environment**.

Generally, after an airport project is identified through the planning process, but prior to moving into the design and construction phase, an environmental analysis such as this Environmental Assessment (EA) is required by the National Environmental Policy Act (NEPA) of 1969. The results of this EA, including input from federal, state, and local agencies, and the public, will guide the decisions made by the FAA and MDOT AERO. At that time, the project may be cleared to proceed with final design and construction or will be required to undergo additional environmental analysis.

1.2 Proposed Action

The Airports Proposed Action (i.e. project) is XXX

The major Federal Action includes the federal funding of the construction of XXXX, and the unconditional approval of the ALP for the project. This includes:

- Unconditional Approval of the portion of the ALP that depicts the components of the proposed project and its connected actions pursuant to 49 USC 40103(b), 44718, and 47101(a)(16), and Title 14 CFR Parts 77 and 157.
- Determination of eligibility for federal assistance under the federal grant-in-aid program authorized by the Airport and Airway Improvement Act of 1982, as amended (49 USC 47101, et seq).
- Approval of an application for federal assistance for eligible components of the proposed project using federal funds from the AIP.

Commented [LS(2]: Please note that this would include those components of the project that were identified in the 163 determination letter that the FAA has authority over. In addition, any elements of the project that the FAA does not have authority over but DEPENDS UPON those components of the project that the FAA has authority over is included in the NEPA analysis, as noted in the first bullet. In Chapter 2, it will be more clear when you list those items of the project and its connected actions.

1.32 Project Purpose and Need for the Proposed Action

1.3.1 Purpose of the Proposed Action

The purpose of the Airports proposed action project is to improve operational utility of the Airport by meeting the takeoff and landing distance requirements of aircraft that currently operate at the Airport and are projected to steadily increase operations over time. ARB is also proposing to enhance safety by providing a clear line-of-sight for ATCT personnel resulting in an unobstructed view of the north end of Taxiway A as shown on **Figure 1.2 Existing Airfield Configuration**.

The purpose of the proposed project is to also revise the existing Airport Layout Plan (found in **Appendix X ALP**) to confirm that proposed alterations do not adversely affect the safety, utility, or efficiency of the Airport. Pursuant to 49 U.S.C. §47107(a)(16)(B), the FAA (under authority delegated from the Secretary of Transportation) will review and approve or disapprove only those portions of the project (or any subsequent revision to the project) that materially impact the safe and efficient operation of aircraft at the Airport or that would adversely affect the safety of people or property on the ground adjacent to ARB as a result of aircraft operations, or that adversely affect the value of prior federal investments to a significant extent.

1.3.2 Need for the Proposed Action

The following objectives will be used to evaluate alternatives on how they best support the need for the proposed action(s):

~~1.2.1~~1.3.2.1 Meet Runway Requirements of Current and Future Users

The proposed ~~project~~ action is needed because Runway 6/24 was designed to serve primarily small piston driven aircraft; however, the Airport receives regular use by small turboprop and business jet aircraft that require a longer runway to operate at a greater capacity than they do today.

Analysis of current Airport operations found that aircraft with similar operational performance characteristics routinely use ARB and have runway requirements that exceed the current 3,505-foot length of Runway 6/24 under standard operating conditions. For these users to conduct operations on the existing runway length, undue concessions in reduced fuel, passengers and/or cargo loads are often needed. Diversions to other airports are also commonly needed when runway surfaces are contaminated with snow or ice, or during the summer months when higher temperatures reduce aircraft performance. Higher temperatures cause ambient air to thin thus requiring longer runway lengths for landing and takeoff operations. ~~FAA Advisory Circular (AC) 150/5325-4B *Runway Length Requirements for Airport Design*, states "*The design objective for the main primary runway is to provide a runway length for all airplanes that will regularly use it without causing operational weight restrictions.*"~~

To document and justify the need to provide enhanced Airport facilities for current and future users of the Airport, FAA and MDOT AERO reviewed a report titled *Runway 6/24 Extension Justification Study* (Study) that was completed in 2021 (found in **Appendix X Runway Justification Study)**. The Study documented the types of aircraft that operate at ARB and then determined the number of current and projected operations ARB could expect in the future. The Study then developed prudent and feasible alternatives to meet the performance requirements of current and future users of the Airport. The intent of the Study was to document, justify, and recommend alternatives to meet the demands of aircraft types regularly using ARB, including operating weight, takeoff on a hot day, and landing on a contaminated (ice or snow) runway.

An important aspect of the Study that helped determine that Runway 6/24 was inadequate for existing and future users started with the identification of a grouping of aircraft types with similar performance characteristics that conduct~~ed~~ at least 500 annual operations at ARB. ~~Aircraft with at least 500 annual operations are known as the critical aircraft.~~ As stated in FAA AC 150/5000-17, *Critical Aircraft and Regular Use Determination*, ~~the FAA also supports the grouping of aircraft types to determine the critical aircraft. FAA guidance states that~~ the critical aircraft for an airport may be a single type of aircraft or a grouping of types of aircraft with similar characteristics that conducts at least 500 annual operations at an airport. The performance requirements of critical aircraft help determine runway length needs.

Commented [LP(3]: Section 6.3, Recommended Runway Length, of the justification study notes that, "The inclusion of the contaminated runway length distances cannot be used to justify runway length under FAA funding requirements; rather, these runway length needs are included to demonstrate the benefit additional runway length would provide when contaminates are present on its surface." Recommend clarifying that contaminated runways are not used in the runway length requirements and discussion is included just as an additional benefit.

Commented [LP(4]: Recommend deleting this quote from the AC. The reference is being taken out of context to indicate that the FAA standard is to design a runway without causing operational weight restriction and insinuate that there are users taking weight restrictions often. The rate of users taking weight restrictions has not been documented (at least in the justification report). The design approach used in the 2 approaches taken in the justification report also have different guidelines and approaches dependent on aircraft MTOW.

Commented [LP(5]: These 3 sentences all repeat the same information about critical aircraft being a single or group that conducts at least 500 ops. Recommend condensing to a single sentence.

The results of the Study found that the Airport Reference Code (ARC) classification of B-II aircraft types are the most demanding grouping of aircraft that currently conduct more than 500 operations per year at ARB. Thus, the Study concluded that existing and future critical aircraft for the design of Runway 6/24 is B-II aircraft. With this understanding, a runway length that meets the demands of B-II aircraft is needed at ARB.

As shown in **Table 1-1 Current and Future Operations by ARC Classification**, the ARC grouping of B-II aircraft types includes both jet and turboprop aircraft types.

AIRPORT REFERENCE CODES (ARC)

Aircraft Approach Category (AAC)

- Category A: Aircraft approach speed less than 91 knots
- **Category B: Aircraft approach speed 91 knots or more but less than 121 knots**
- Category C: Aircraft approach speed 121 knots or more but less than 141 knots
- Category D: Aircraft approach speed 141 knots or more but less than 166 knots
- Category E: Aircraft approach speed 166 knots or more

Airplane Design Group (ADG)

- Group I: Wingspan less than 49 feet
- **Group II: Wingspan 49 feet or more but less than 79 feet**
- Group III: Wingspan 79 feet or more but less than 118 feet
- Group IV: Wingspan 118 feet or more but less than 171 feet
- Group V: Wingspan 171 feet or more but less than 214 feet
- Group VI: Wingspan 214 feet or more but less than 262 feet

Note: ARB classifications are in **bold** and underlined.
Source: FAA AC 150/5300-13A, *Airport Design*

The forecasts of future aviation operations prepared as part of the Study also indicated that B-II small turboprop and jet aircraft operations will slowly increase over time at ARB. Understanding that this demand will increase also supports the need of providing improved B-II facilities. Thus, it is prudent for ARB to meet B-II critical aircraft standards to accommodate, in whole or part, both turboprop and jet aircraft on Runway 6/24.

Providing a B-II runway would meet the operational demands of current and future users by eliminating weight concessions and allowing aircraft to operate at greater capacities, thus resulting in a more efficient operating environment. For details of the runway justification process including operations, forecasts, runway length analysis, alternatives, and recommendations see **Appendix X Runway Justification Study**.

Table 1-1 Current and Future Operations by ARC Classification

Physical Class	Representative Aircraft	Representative ARC	2019	Forecasts			
				2023	2028	2033	2038
Jet	C56X - Excel XLS	B-II*	263	283	302	321	338
Jet	E55P - Phenom 300	B-II*	97	104	112	118	125
		Subtotal Jets	**360**	**387**	**414**	**439**	**462**
Turbine	TBM8 - TBM-850	A-I	150	161	172	183	193

		Subtotal Turbine	**1,116**	**1,201**	**1,283**	**1,361**	**1,434**
Piston	C172 - Cessna 172	A-I	2,876	3,016	3,225	3,427	3,613
		Subtotal Piston	**2,876**	**3,106**	**3,225**	**3,427**	**3,613**
Other	EC55 - EC-155	n/a	67	70	75	80	84
		Subtotal Other	**67**	**70**	**75**	**80**	**84**

~~1.2.2~~1.3.2.2 Provide an Unobstructed View of the Taxiway A

The proposed project is also needed to address obstructed views of the northern end of Taxiway A from the ATCT. Currently, there is limited visibility of the intersection of Taxiway A and Connector Taxiway A1 (illustrated on **Figure 1.2 Existing Airfield Configuration)** by personnel working in the ATCT. Lack of visual supervision of taxiing aircraft can lead to movement complications and miscommunications.

Source: FAA TFMSC database (2019), Projections: Mead & Hunt, Inc. (2020)

* Denotes B-II aircraft groupings operating at ARB

There are two hangars located north of Taxiway A that obstruct the view from the ATCT. This condition fails to meet FAA guidance regarding visibility of the movement area of an airfield. According to FAA AC Order 6480.4B, *Airport Traffic Control Tower Siting Process*, the entire movement area of the airfield should be observable from the ATCT to control aircraft movement and operations in a safe and efficient manner. Under existing conditions, this criterion is not met.

By providing a clear line-of-sight from the ATCT, air traffic controllers will have an unobstructed view of the entire length of Taxiway A. This improved condition will enhance safety of ground operations by taxiing aircraft and improve the overall utility for users of the Airport.

1.~~3~~4 Summary of Existing and Projected Operations

As part of the *Runway 6/24 Extension Justification Study* described above, historical and future trends of aviation activity were completed for ARB. The Study analyzed past, current, and projected operations from 2005 through the year 2039 and found that passenger and aircraft activity at the Airport have fluctuated in recent history. This is not uncommon in comparison to many U.S. airports as economic uncertainty and increased travel costs have impacted aviation usage.

It should be noted that the economy of the United States and the aviation industry had a near complete shutdown in April 2020 due to the COVID-19 pandemic. The pandemic greatly impacted operations at ARB. However, operations have rebounded quickly and now nearly match the totals from 2018 and 2019. Therefore, it is anticipated that operations will fully recover to pre-COVID levels in 2021.

A summary of the forecasts is presented in **Table 1-2 Projections Summary**. These figures illustrate that there is anticipated gradual growth in aircraft activity at ARB with total operations expected to increase from the 2019 level of 76,428 to 84,336 in 2039. For details of existing and projected aviation forecasts at ARB see **Appendix X Runway Justification Study**.

Table 1-2 Projections Summary

	Itinerant Operations			Local Operations			
Year	Air Taxi	General Aviation	Military	General Aviation	Military	Total Operations	Based Aircraft
Historical							
2005	2,105	24,942	17	40,871	5	67,940	164
2006	2,082	26,530	263	42,910	0	71,785	148

1.5 Required Environmental Review

REPLACE TEXT WITH INSERT FROM RST PREPARED BY MEAD and HUNT AND COMPLETED LEGAL SUFFICIENCY REVIEW

Federal financial participation in projects through the Airport and Airway Improvement Act of 1982 (AIP), requires environmental review under the National Environmental Policy Act (NEPA). In addition, FAA must approve the Airport Layout Plan (ALP) elements associated with the proposed action evaluated under NEPA. An Environmental Assessment (EA) is a document prepared under NEPA that evaluates the effects of a proposed action on the surrounding natural, social, and economic environments. This EA is prepared under the requirements of the Title V of Public Law 97-248 of the Airport and Airway Improvement Act of 1982, NEPA, and FAA Order 5050.4B, *National Environmental Policy Act Implementing Instructions for Airport Actions* (April 2006). The EA also meets the requirements of FAA Order 1050.1F, *Environmental Impacts: Policies and Procedures,* dated July 2015.

The intent of the EA is to provide the environmental documentation necessary to assist local, state and federal officials in evaluating the proposed action at RST. The EA evaluates the proposed action and a full range of alternatives to the proposed action that meet the purpose and need identified in the EA. The analysis also identifies and discusses measures to avoid, minimize, and mitigate possible environmental impacts.

The EA is prepared to comply with NEPA. The FAA must evaluate the EA under NEPA and, if the project does not have the potential for significant impacts, issue a Finding of No Significant Impact (FONSI), or if it does have significant impacts, prepare a federal Environmental Impact Statement (EIS).

Rochester International Airport / Draft EA 1

~~The Airport is subject to federal and state environmental review because it is a federally obligated airport and must meet its federal grant assurance requirements. The proposed Airport improvements require an environmental evaluation be prepared under the direction of NEPA. NEPA requires any action that involves federal funding or federal permits undergo an environmental analysis that evaluates and documents the effects of the proposed project on the surrounding natural, social, and economic environment.~~

~~The intent of this EA is to provide the environmental documentation necessary to assist local, state, and federal agencies in evaluating the proposed development in a brief and concise format documenting only information deemed relevant to the project. Any information used from other studies or reports will be referenced only, directing the reader to other sources for more information as applicable.~~

~~This EA is being developed to determine whether any potential impacts associated with the proposed action are significant enough to necessitate a greater level of environmental analysis that would be typically achieved through an Environmental Impact Statement (EIS) or additional technical studies.~~

~~The proposed action will be evaluated, along with a range of alternatives that includes a No-Build/Do Nothing alternative to identify a Preferred Alternative that meets the project's purpose and need. This analysis will also include measures to avoid, minimize, and mitigate possible adverse environmental impacts associated with the Preferred Alternative.~~

~~This EA has been prepared in accordance with the requirements of NEPA, FAA Order 5050.4B, *NEPA Instructions for Airport Actions*, and FAA Order 1050.1F, *Environmental Impacts Policies and Procedures*,~~

42 U.S.C. 4332(2)(c), 49 U.S.C. 3030, 23 U.S.C. 138, and Council on Environmental Quality (CEQ) guidelines.

1.6 Requested Federal Action

This EA will be submitted to the FAA and MDOT AERO for evaluation. If the agencies conclude the proposed action will not cause a significant environmental impact, they may issue a final federal environmental determination. If it is found that a major or significant impact will result from the proposed action, the FAA / MDOT AERO may request additional environmental review or not approve the project.

1.7 Projected Time Frame of Improvements

The proposed project timeframe (pending available funding and approval of this EA) is:

- Final EA submitted for review and approval: Winter 2022
- Project design begins: Spring 2022
- Project construction begins: Fall 2022

Chapter 2.0 Alternatives Considered - DRAFT

2.1 Introduction

In accordance with the Council on Environmental Quality (CEQ) regulations found in 40 Code of Federal Regulations (CFR) § 1502.14(d), an environmental review process requires that ~~prudent and feasible~~reasonable alternatives be identified and evaluated that might accomplish the objectives of a proposed project. This requires the FAA to identify potential alternatives that are available to achieve the purpose and need for a given project and present the basis used to make an informed decision regarding the selection of a Preferred Alternative .

~~As the lead federal agency, the Federal Aviation Administration (FAA) is responsible for complying with the policies and procedures of the National Environmental Policy Act (NEPA) of 1969 and other related environmental laws, regulations, and orders applicable to FAA actions. This requires the FAA to identify potential alternatives that are available to achieve the purpose and need for a given project and present the basis used to make an informed decision regarding the selection of a Preferred Alternative.~~

NEPA and FAA regulations do not require the inclusion of a specific number of alternatives or a specific range of alternatives in an Environmental Assessment (EA). However, an EA must consider the proposed action and the consequences of taking no action. For alternatives that were considered but eliminated from further study, the airport must briefly explain why such alternatives were eliminated from further consideration.

Pursuant to FAA regulations set forth in Order 1050.1F, *"Environmental Impacts: Policies and Procedures,"* an alternatives discussion should include:

- A list of alternatives considered, including the proposed action and the no action alternative
- Any connected ~~or cumulative~~ actions associated with each alternative
- A concise statement explaining why any initial alternatives were eliminated from further study
- A statement identifying a Preferred Alternative if one has been identified
- Any other applicable laws, regulations, executive orders and associated permits, licenses, approvals, and reviews required to implement a project alternative

This chapter documents different options that may reasonably meet the needs of the proposed project at the Ann Arbor Municipal Airport (ARB or Airport), as explained in **Chapter 1.0 Purpose and Need**. It should be noted that preliminary costs for build alternatives are provided; however, comprehensive costs will be developed during the final design of the Preferred Alternative.

See **Appendix XX Runway Justification Study** for aircraft types that operate at ARB and the number of current and projected operations the Airport can expect in the future. This study also helped in developing build alternatives to meet the project's purpose and need.

Commented [LS(1]: I do not believe that there are 4f impacts – if there is, please keep the prudent and feasible terminology with some reference to Section 4(f); if not 4(f) resource, please replace with "reasonable"

Commented [LS(2]:

Commented [LS(3R2]:

Commented [LS(4]:

Commented [FJ(5]: Would be redundant to chapter 1.

Commented [LS(6]: Typically you are unable to do so until going thru the environmental impacts analysis so it is not necessarily appropriate to imply that this is required in chapter 2.

Commented [LS(7]: 1050 4.2.d refers to the types of impacts that are described in the environmental impacts chapter (direct/indirect/ and cumulative).

Commented [LS(8]: i.e whether the alternative(s) were not considered reasonable (did not meet the purpose and need).

The following alternatives are presented and discussed in this chapter:

- ➢ No Build ~~(Do Nothing)~~ Alternative – Maintain Existing 3,505 Feet of Runway Length
- ➢ Build Alternatives:
  - Alternative 1 – Extend 720 Feet at the Approach End of Runway 24
  - Alternative 2 – Shift Runway 150 Feet Southwest and Extend 720 Feet at the Approach End of Runway 6
  - Alternative 3 – Extend 360 Feet at both ends of Runway 6/24

> **Commented [LS(9]:** The no build alternative maintains the existing runway; therefore it is not a do nothing or no action alternative.

2.2 Safety Areas and FAA Design Standards

Safety areas, as defined by the FAA in Advisory Circular (AC) 150/5300-13A, Change 1, *Airport Design*, are of importance in evaluating potential alternatives because they are a controlling factor for each runway end and for determining potential impacts. This section includes a definition of the different safety areas important to this project and required by FAA design standards.

Runway Safety Area (RSA): The RSA is a two-dimensional graded area surrounding the runway surface and is constructed to enhance the safety of airplanes in the event of an unintended excursion from the runway's paved surface. This area must be:

- Cleared and graded with no potentially hazardous humps, ruts, depressions, or other surface variations
- Adequately drained to prevent water accumulation
- Capable of supporting snow removal equipment, rescue and firefighting equipment, and occasional aircraft passage without causing structural damage to the aircraft
- Free of objects, except for those that need to be in the RSA because of their function, and then, to the extent practical, mounted on low impact (frangible) structures
- Capable, under normal (dry) conditions, of supporting airplanes without causing structural damage to the airplanes or injury to their occupants

> **Commented [LP(10]:** Recommend using wording from the Design AC Section 307.b.(3), "Capable, under dry conditions, of…"

> **Commented [LP(11]:** This may be redundant to 3rd bullet. While injury to occupants is discussed in the historic development of the RSA section of the Design AC (307.a.(1)), the wording in the Design AC standards section (307.b.) is captured in the 3rd bullet.

Runway Object Free Area (ROFA): A ROFA is a two-dimensional ground surface surrounding a runway. The ROFA clearing standards preclude above ground objects protruding above the RSA edge elevation, except those required to be within the ROFA for navigation, ground maneuvering, aircraft taxi, and aircraft holding purposes. No other objects are permitted.

> **Commented [LP(12]:** Recommend using "protruding above the nearest point of the RSA," language from the Design AC (Section 309) rather than "RSA edge elevation"

Runway Protection Zone (RPZ): The RPZ is a trapezoidal shaped area centered on the extended runway centerline and extended off each runway end. The function of an RPZ is to enhance the protection of people and property on the ground~~, protect airspace,~~ and prevent incompatible land uses. Airports are encouraged by the FAA to control the land within an RPZ to clear RPZ areas of incompatible objects and activities ~~prevent the creation of hazards to landing and departing aircraft.~~

> **Commented [LP(13]:** Recommend deleting reference to "protecting airspace." Protecting airspace is not a function identified in Design AC RPZ section (310).

> **Commented [LP(14]:** Recommend deleting and replacing with "clear RPZ areas of incompatible objects and activities." This more closely matches language in the Design AC (Section 310)

To determine potential RPZ impacts of the proposed project, a separate technical report (RPZ Analysis) was completed for Runway 6/24 and found in **Appendix XX RPZ Analysis**. The RPZ Analysis evaluated land uses within the RPZs of each build alternative to determine incompatible land uses. The findings of each build alternative are included below.

2.3 No-Build Alternative – Maintain Existing 3,505 Feet of Runway Length

The No-Build Alternative assumes that no action would be taken to address the needs of the Airport as identified in **Chapter 1.0 Purpose and Need**. Under this alternative, ARB would remain in its current state with no plans to meet the documented needs of current and future users for a longer runway. Under this alternative, the limited visibility of the intersection of Taxiway A and Connector Taxiway A1 experienced by the air traffic control tower (ATCT) would remain unchanged.

The No-Build Alternative does not meet the project's purpose and need of providing an air transportation facility that meets the takeoff and landing distance requirements of aircraft that currently operate at the Airport and are projected to steadily increase operations over time ~~that complies with FAA Advisory Circular (AC) 150/5325-4B *Runway Length Requirements for Airport Design*~~ and provide a clear line-of-sight for ATCT personal as defined in FAA AC Order 6480.4B, *Airport Traffic Control Tower Siting Process*.

Although the No-Build Alternative does not meet the purpose and need of the proposed project, it does serve as a baseline of comparison for environmental impacts associated with other build alternatives and is, therefore, retained for analysis and carried forward for review.

2.4 Alternative 1 – Extend 720 Feet at the Approach End of Runway 24

Under this alternative, Runway 6/24 would be extended 720 feet to the northeast at the approach end of Runway 24 to provide a total length of 4,225 feet of available runway length (**Figure 2.1 Alternative 1 – Extend 720 Feet at the Approach End of Runway 24**). Taxiway A would be extended to match the runway extension and a new connector taxiway (Taxiway A1) would be constructed to align with the relocated threshold of Runway 24. Existing Taxiway D would also be reconstructed to match the runway extension and be designed to intersect Runway 6/24 at a 90-degree angle. All applicable navigational aids (NAVAIDs), lighting, and signage would be relocated to match the proposed runway extension and would meet FAA design standards.

Taxiway D would be realigned so that it has a standard 90-degree intersection with Runway 6/24 to comply with FAA AC 150/5300-13A Change 1, Section 401.b.(5).(g) *Indirect Access* (herein referenced as Indirect Access). FAA design standards discourage direct access from an apron to a runway without requiring a turn by aircraft prior to reaching the runway. Direct access configurations can lead to confusion when pilots expect to maneuver onto a parallel taxiway but instead enter a runway.

This alternative would also require State Street to be reconstructed outside of the relocated Taxiway D, the RSA, and the ROFA. The existing roadbed of State Street through these areas would be closed and the pavement removed. Two options for relocating State Street are shown on **Figure 2.1 Alternative 1 –**

Commented [LP(15]: Per the Interim Guidance on Land Uses Within a Runway Protection Zone, (September, 2012) the RPZ Alternatives Analysis identifies and documents the full range of alternatives that could
1. Avoid introducing the land use issue within the RPZ
2. Minimize the impact of the land use in the RPZ
3. Mitigate risk to people and property on the ground.

Did the RPZ analysis evaluate the 3 items above, or did it only determine incompatible land uses?

Commented [LS(16]: For each alternative, it may be helpful to have a subsection for each item from the purpose/need statement so that it is clear whether the alternative is reasonable (meets the purpose and need for the proposed project).

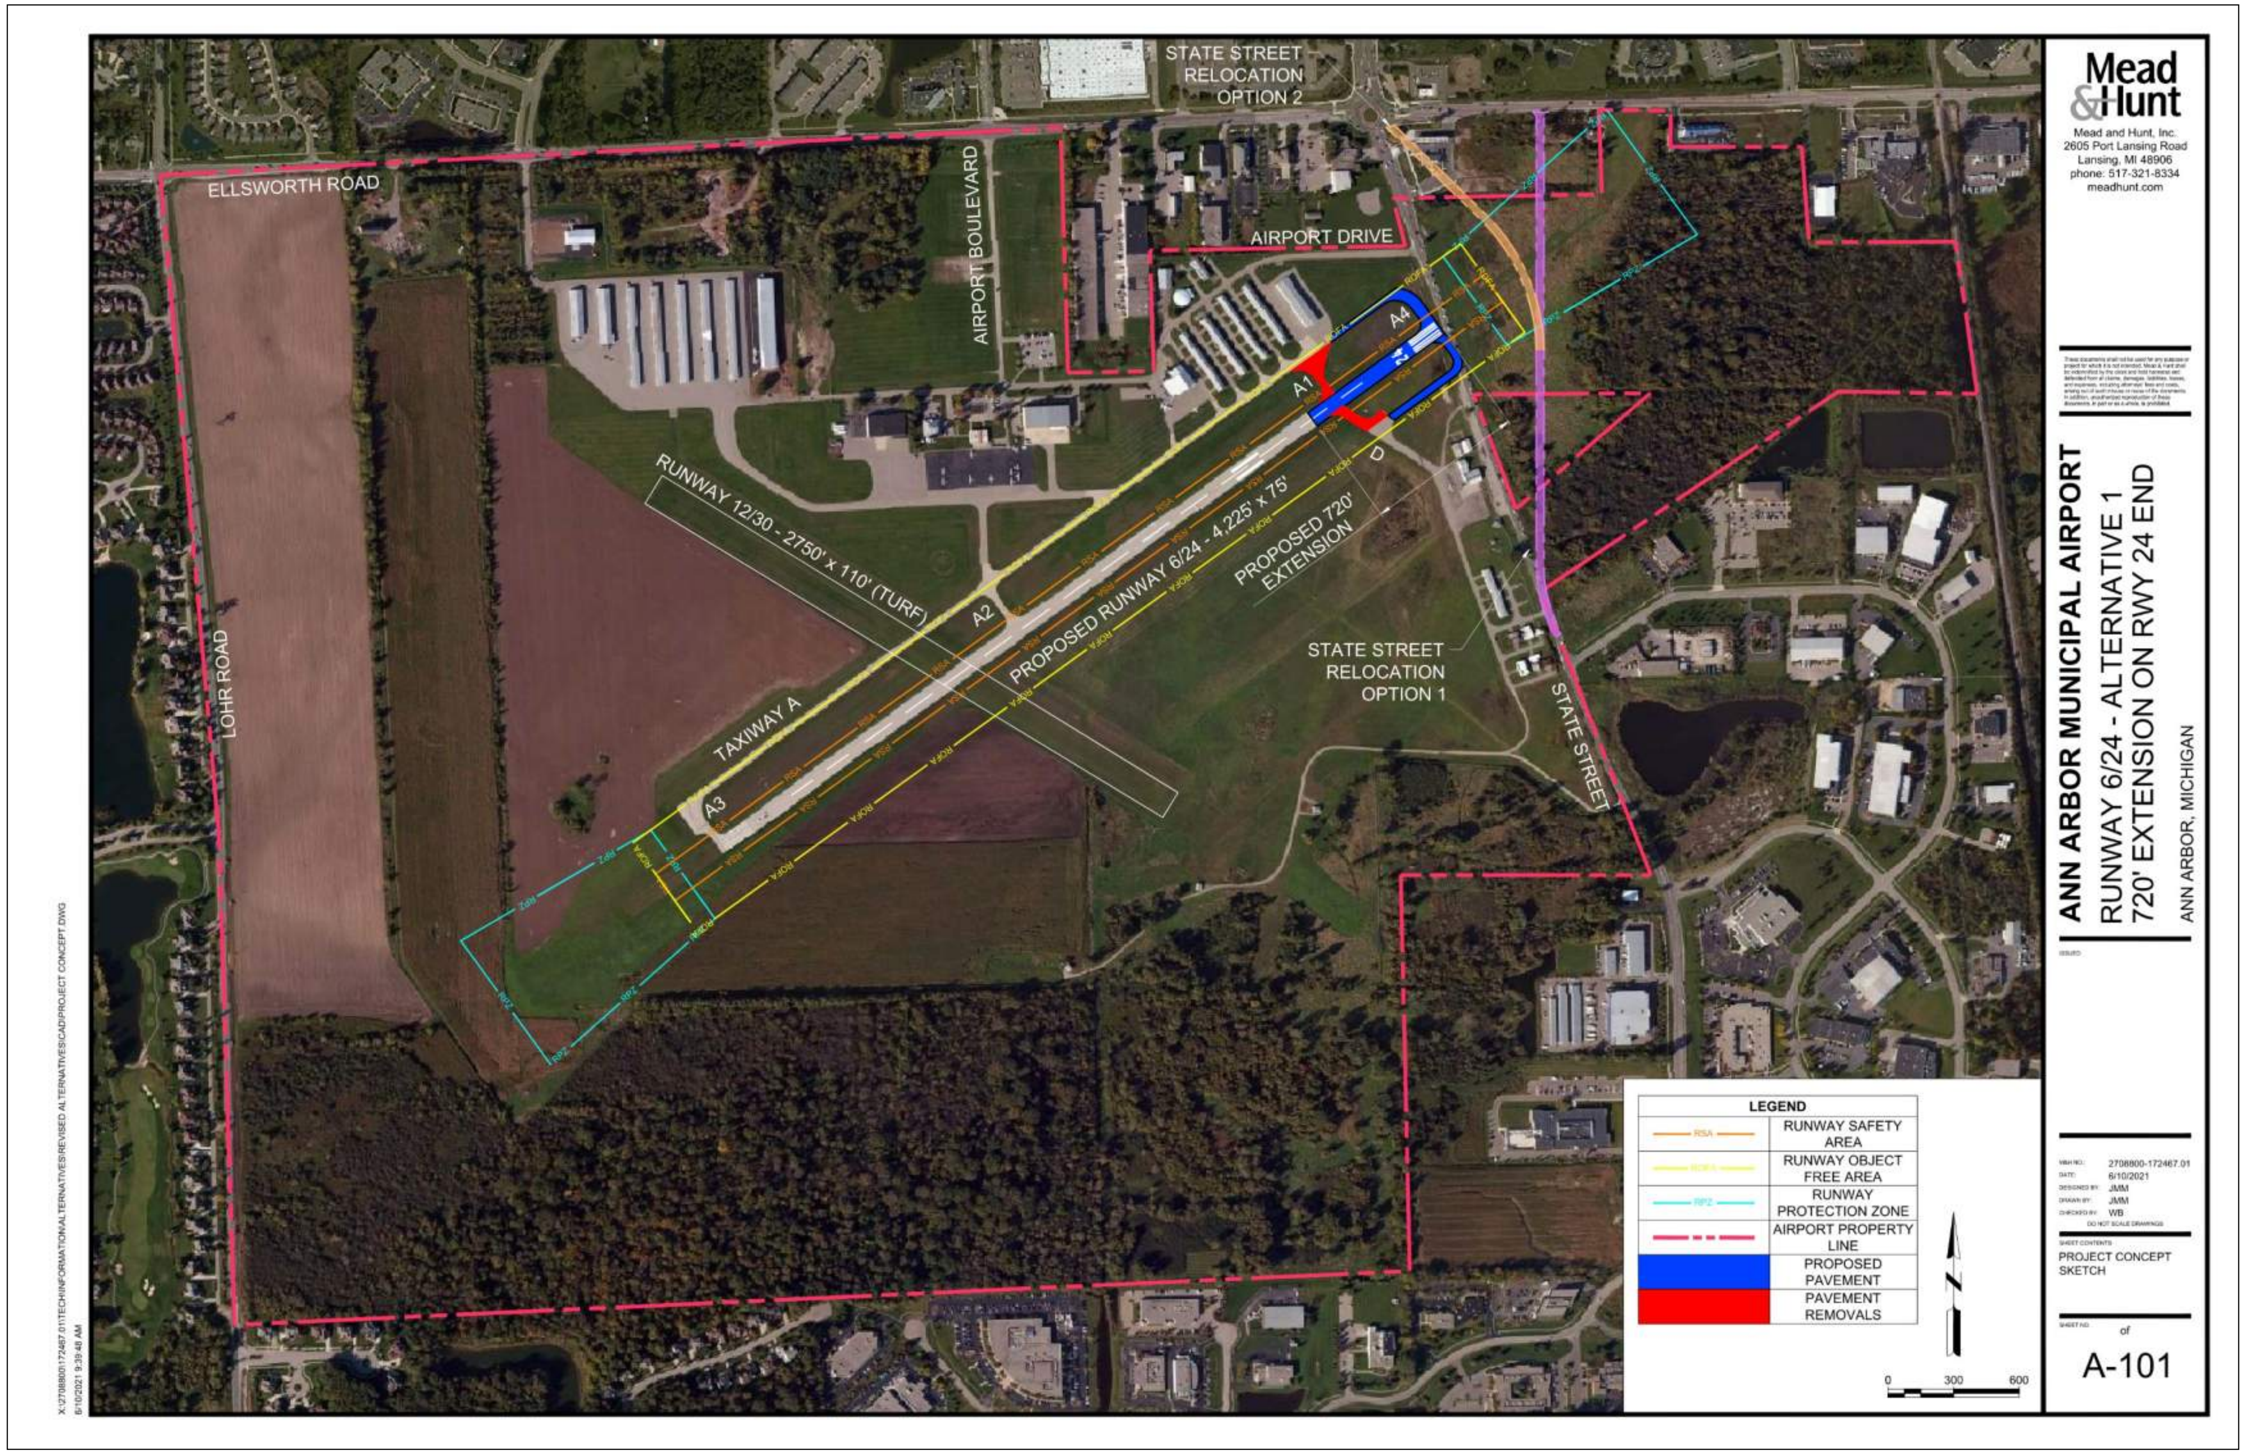
2.3.1 Meet Runway Requirements for Current and Future Users
2.3.2 Provide Unobstructed Views of Taxiway A

Commented [LP(17]: Recommend deleting reference to the FAA Runway Length AC and matching the P&N Section 1.3.1, "The purpose of the Airports proposed action is to improve operational utility of the Airport by meeting the takeoff and landing distance requirements of aircraft that currently operate at the Airport and are projected to steadily increase operations over time"

Extend 720 Feet at the Approach End of Runway 24. Any property that is not owned or controlled by ARB within the RSA and ROFA would require either acquisition or an avigation easement.

As previously mentioned, a separate RPZ Analysis evaluated land uses within the relocated RPZ off the end of Runway 24. The analysis found few incompatible land uses beyond the two State Street relocation options. Generally, roads within an RPZ are undesirable and should be avoided, if possible.

Figure 2.1 Alternative 1 – Extend 720 Feet at the Approach End of Runway 24



Source: Mead & Hunt, Inc.

Preliminary investigations indicate that regulated wetlands are found throughout the area east of State Street. It is likely that both State Street alignment options would cause impacts to regulated wetlands.

The primary advantage of Alternative 1 is that it offers 4,225 feet of usable runway length that meet the needs of existing turboprop and jet aircraft that currently operate at the Airport and are forecasted to grow modestly in the future. This alternative would also realign Taxiway D so that it has a standard 90-degree intersection with the Runway 6/24 to comply with FAA AC 150/5300-13A, Change 1.

Disadvantages of Alternative 1 include the relocation of State Street around the approach end of Runway 24 and its associated RSA & ROFA surfaces. The State Street relocation would also cause business and private property impacts where it connects to Ellsworth Road, likely causing land and commercial acquisitions. Also, there may be considerable community, road, and wetland impacts during construction and realignment of State Street.

Commented [FJ(18]: Will there be tree removal impacts?? Acreages if so?

Another disadvantage of Alternative 1 is that the ATCT will continue to have visibility deficiencies at the intersection of Taxiway A and connector Taxiway A1 when aircraft and ground vehicles are in the area. According to FAA AC Order 6480.4B, *Airport Traffic Control Tower Siting Process*, the entire movement area of the airfield should be observable from the ATCT to control aircraft movement and operations in a safe and efficient manner.

Alternative 1 is not considered a ~~prudent and feasible~~ reasonable alternative because it fails to meet the project's purpose and need of addressing visibility issues experienced by the ATCT. Although Alternative 1 provides adequate runway length for current and future users, it fails to provide line-of-sight for the entire movement area of the airfield.

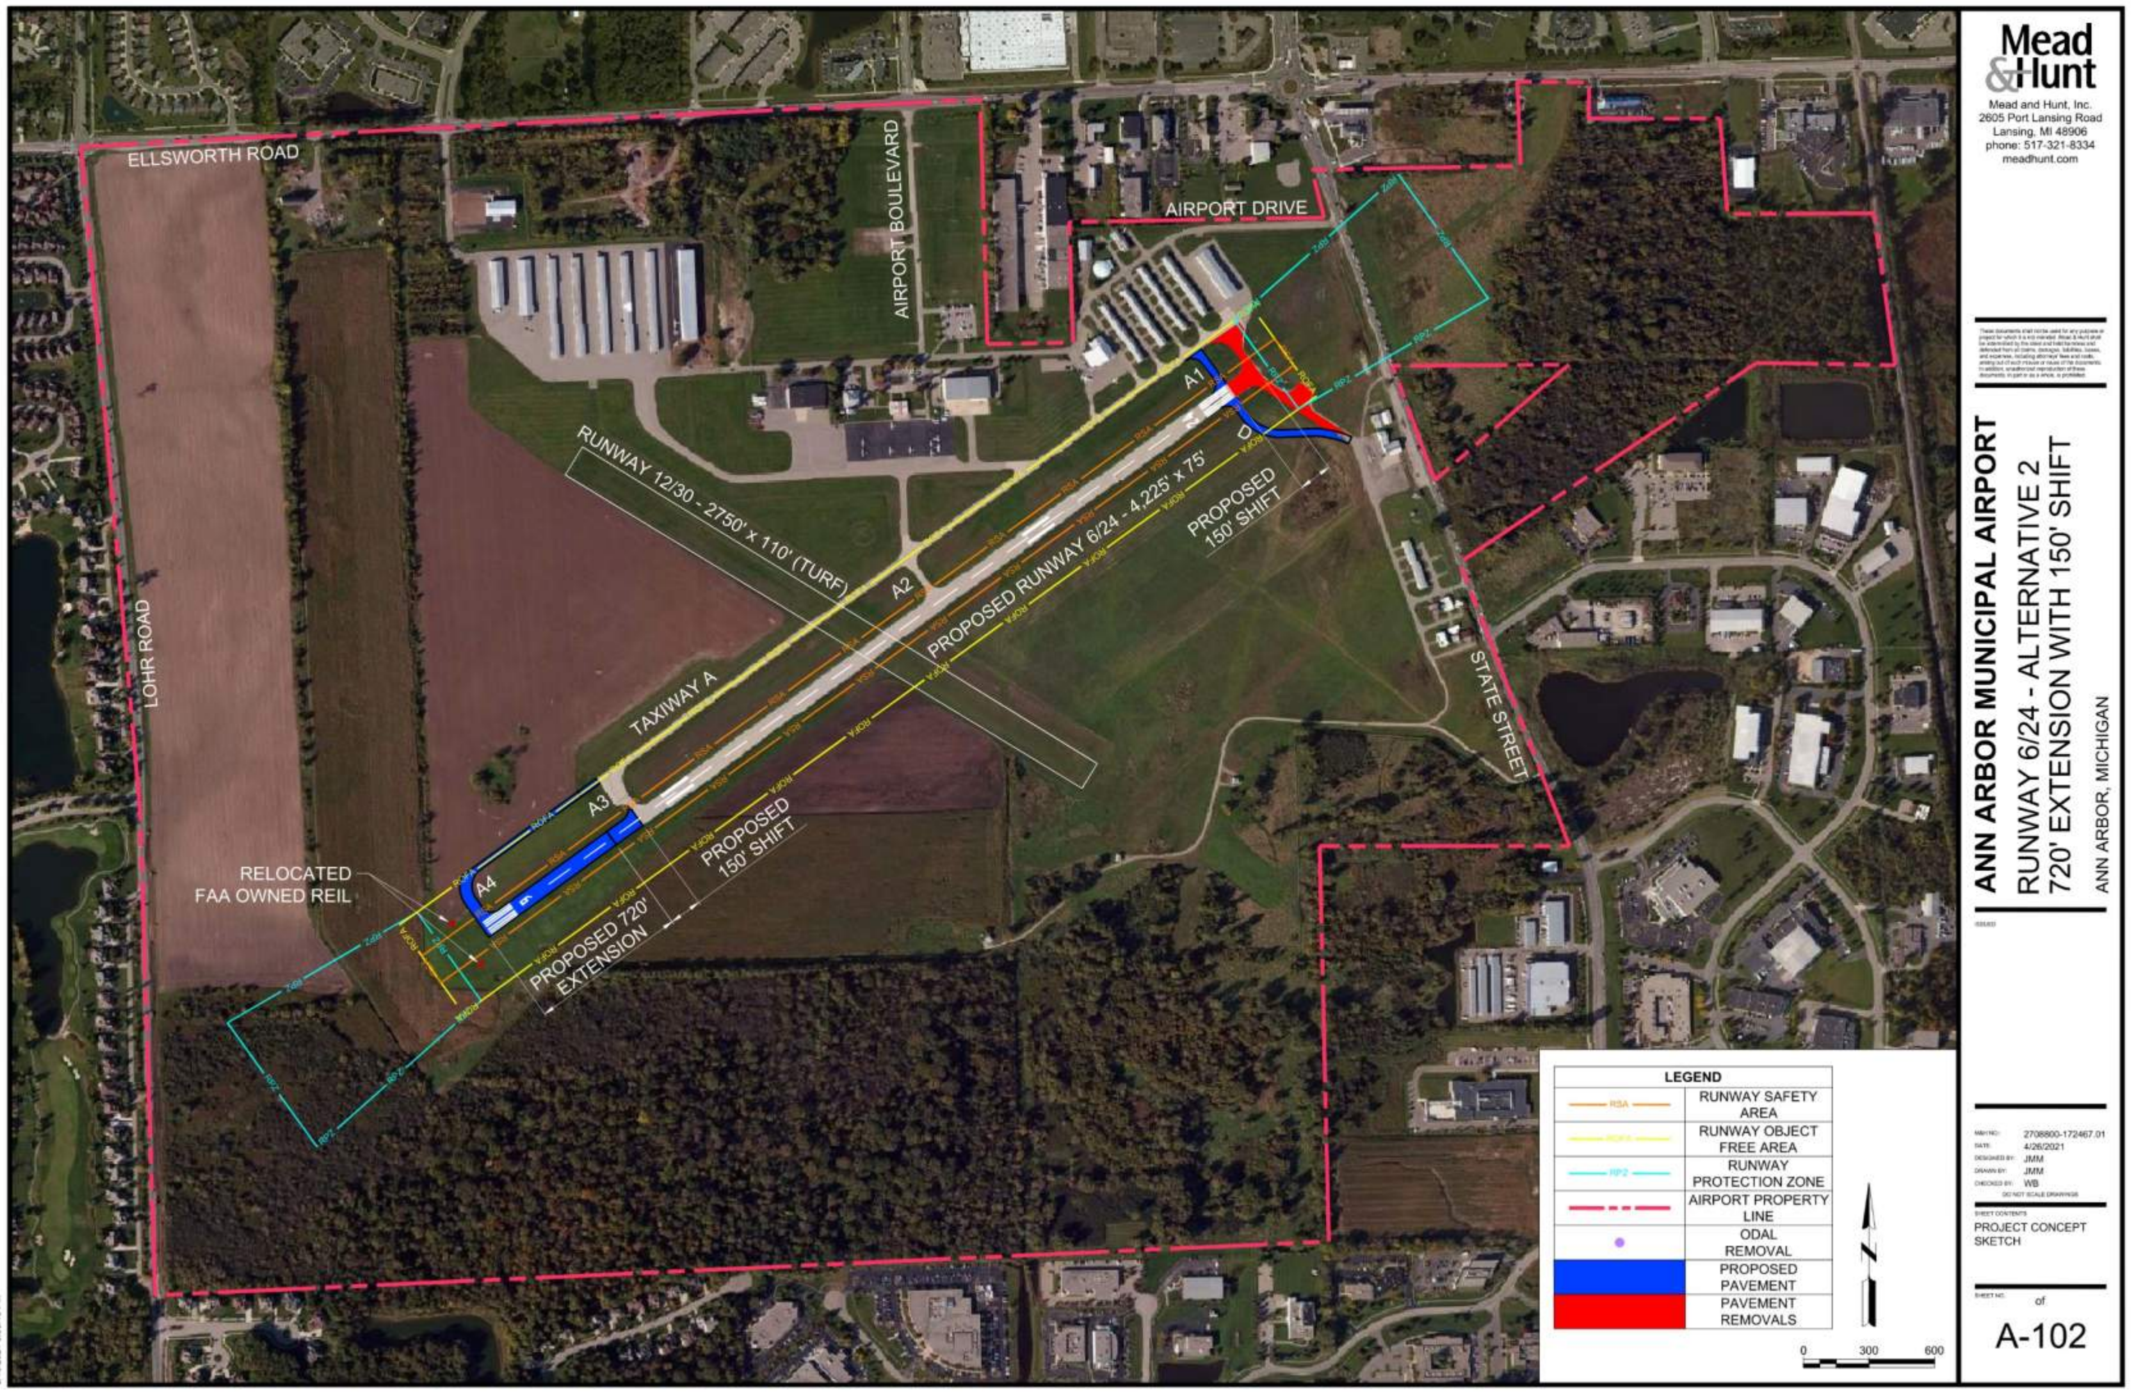
Alternative 1 is the most expensive of the build options, with a preliminary cost estimate of $10.9 million. This alternative is approximately three times more expensive than Alternative 2.

2.5 Alternative 2 – Shift Runway 150 Feet Southwest and Extend 720 Feet at the Approach End of Runway 6

With this alternative, Runway 6/24 would be shifted 150 feet to the southwest and then extended 720 feet at the approach end of Runway 6 to provide 4,225 feet of usable runway length (**Figure 2.2 Alternative 2 – Shift Runway 150 Feet Southwest and Extend 720 Feet at the Approach End of Runway 6**). The shift would be accomplished by constructing an additional 150 feet of runway length at the end of Runway 6 and removing 150 feet of existing pavement at the Runway 24 end. The runway shift would provide clear visibility and line-of-sight of the intersection of Taxiway A and connector Taxiway A1 for ATCT personnel.

Taxiway A would be extended to the southwest to match the additional runway length and a new connector taxiway (Taxiway A4) would be constructed to align with the relocated threshold of Runway 6. All applicable navigational aids (NAVAIDs), lighting systems, and signage would be relocated to match the proposed runway extension and would meet FAA standards including the relocation of existing FAA owned Runway End Identifier Lights (REILs) found at the approach end of Runway 6.

Figure 2.2 Alternative 2 – Shift Runway 150 Feet Southwest and Extend 720 Feet at the Approach End of Runway 6



Source: Mead & Hunt, Inc.

Existing Taxiway D would be relocated 150 feet to the southwest and reconstructed to comply with FAA Indirect Access guidance. This guidance prohibits direct access from an apron to a runway without requiring a turn by aircraft prior to reaching the runway.

Alternative 2 also corrects the geometry of the intersection of Taxiway A1 and Taxiway D with Runway 6/24 so that they intersect Runway 6/24 at right angles. This proposed design reduces pilot confusion and improves situational awareness.

The RPZ Analysis found no incompatible land uses within either runway's relocated RPZ. No RSA or ROFA impacts are expected with this alternative.

Commented [LP(19]: The existing State Street would be considered an incompatible land use.

Commented [FJ(20R19]: But, state street could stay due to RPZ Alt Analysis determination.

There are few environmental concerns or potential impacts associated with Alternative 2. There are two regulated wetlands and a constructed agricultural drainage ditch off the end of Runway 6. Preliminary design indicates that both regulated wetlands can be avoided with no impacts expected. The RSA and ROFA of Runway 6 will intersect a constructed agricultural ditch; however, the ditch flows inside an existing culvert at this location, therefore, ditch impacts are not expected. There is one regulated wetland complex in the vicinity of Runway 24 and proposed relocated Taxiway D. Analysis indicates that the construction of Taxiway D can be designed to avoid impacts to this wetland.

Commented [FJ(21]: Show the wetlands on your exhibit.

Alternative 2 offers many advantages over the other build alternatives. Alternative 2 provides 4,225 feet of needed runway length for turboprop and jet aircraft that currently operate at ARB and are projected to grow moderately in the future. Alternative 2 provides additional runway length entirely within the existing property boundary without requiring the relocation of State Street or causing property or road construction impacts. Although there are regulated environmental resources in the area, impacts to wetlands or agricultural ditches are not expected.

Commented [FJ(22]: Tree impacts?

Additionally, Alternative 2 corrects the geometry of the intersection of Taxiway A1 and Taxiway D with Runway 6/24 so that pilot visibility is maximized thus increasing safety. Shifting the runway 150 feet to the southwest also eliminates the obstructed view from the ATCT so that air traffic controllers can view the entire movement area of Runway 6/24.

This 150-foot shift and runway extension to the southwest also keeps the RPZ at the approach end of Runway 6 and Runway 24 entirely within existing Airport property, eliminating the need for land acquisition or easements to control land uses within these areas. With Alternative 2, a greater percentage of the Runway 24 RPZ will be on ARB property due to the 150-foot shift than previously, thus improving the existing condition and giving the Airport more control of its RPZ.

Commented [FJ(23]: Than previously what? Prior to the project?

While Alternative 2 has many advantageous, one minor disadvantage is the need to relocate the FAA owned REILs at the approach end of Runway 6. This will require the Airport to coordinate with the FAA during final design and construction.

Alternative 2 is considered a ~~prudent and feasible~~ reasonable alternative because it fully meets the project's purpose and need and has minimal community, road, and environmental impacts. Alternative 2 is the least expensive of the build options, with a preliminary cost estimate of $3.1 million. This alternative is considerably less expensive when compared to Alternative 1 and Alternative 3.

2.6 Alternative 3 – Extend 360 Feet at Both Ends of Runway 6/24

Alternative 3 proposes to achieve a runway length of 4,225 feet with the construction of a 360-foot extension on each end of Runway 6/24 (**Figure 2.3 Alternative 3 – Extend 360 Feet at Both Ends of Runway 6/24**). At the approach end of Runway 6, a 360-foot extension of the runway and Taxiway A as well as the construction of a new Taxiway A4 connector, to align with the new runway threshold would be constructed.

At the approach end of Runway 24, a 360-foot extension of the runway and Taxiway A would occur as well as a relocation of Taxiway A1. Existing Taxiway D would be reconstructed to match the runway extension and be designed to intersect Runway 6/24 at a 90-degree angle to address the indirect access issue. Existing pavements of Taxiway A1 and Taxiway D would be removed under this new taxiway configuration.

All applicable navigational aids (NAVAIDs), lighting systems, and signage would be relocated to match the proposed runway extensions at each runway end and would meet FAA design standards including the relocation of existing FAA owned REILs found at the approach end of Runway 6.

With the runway extending to the northeast, State Street would be relocated so its new alignment is constructed around the approach end of Runway 24 and the associated RSA and ROFA surfaces as shown on **Figure 2.3 Alternative 3 – Extend 360 Feet at Both Ends of Runway 6/24**. Much like Alternative 1, this alternative requires State Street to be relocated, but to a lesser degree. Acquisition of land is expected with the relocated State Street and avigation easements within the relocated RPZ at the approach end of Runway 24 for portions outside of the existing airport property will be needed. No RSA or ROFA impacts are anticipated with the 360-foot extension of Runway 6 to the southwest.

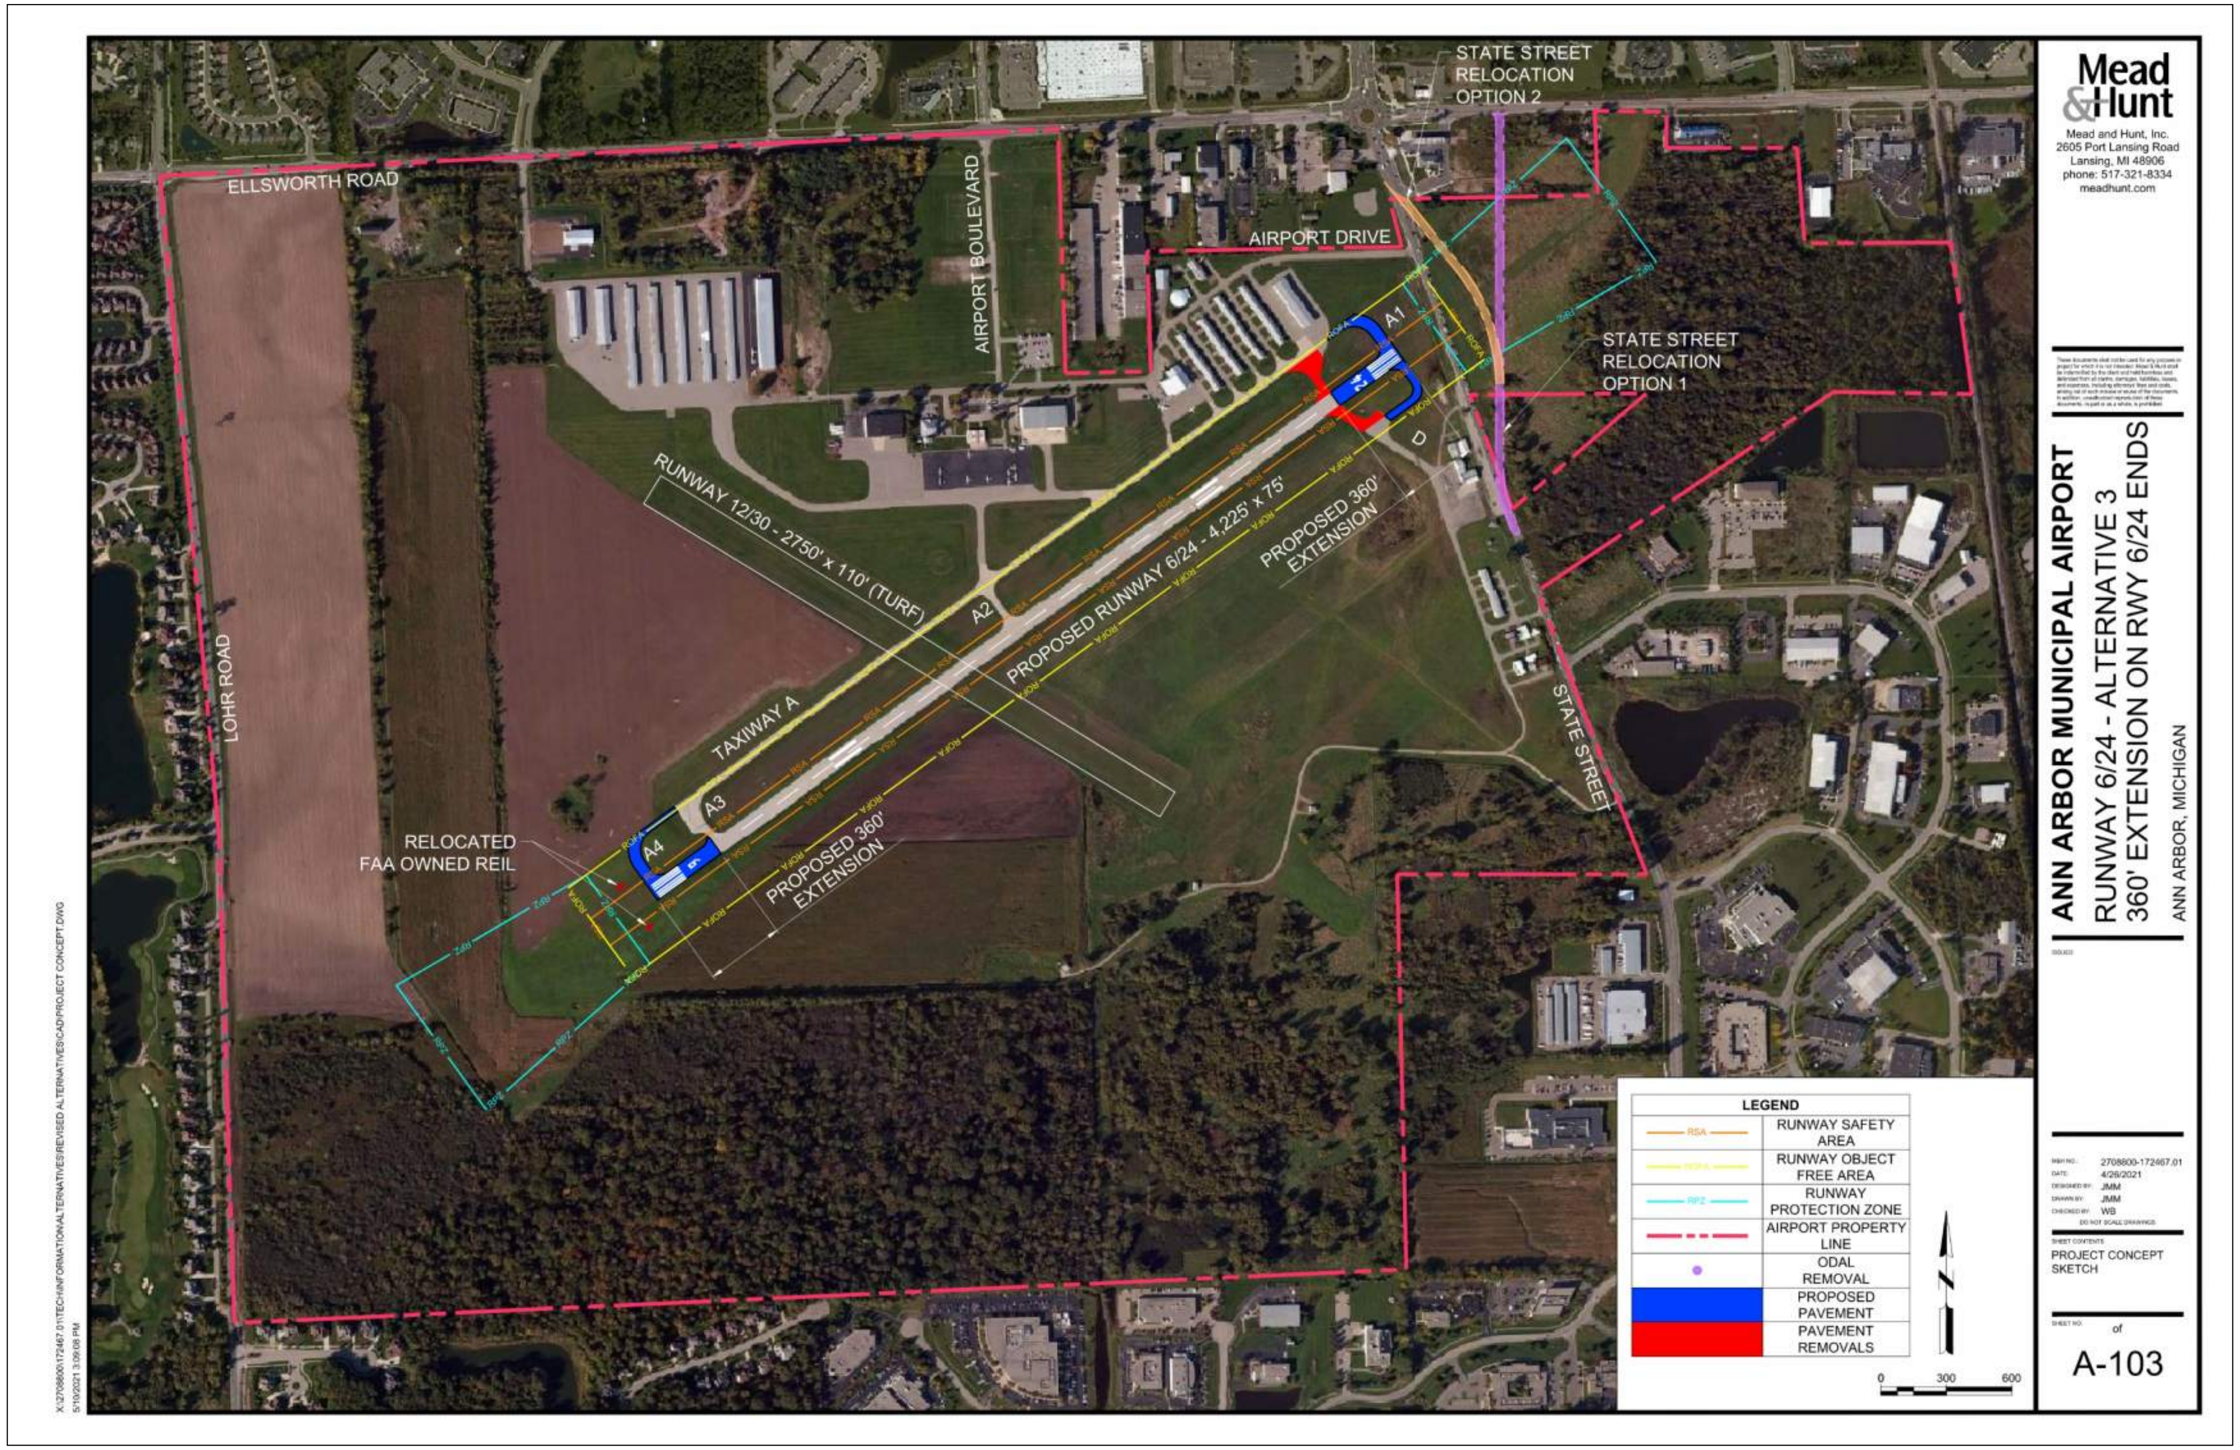
The RPZ Analysis found no incompatible land uses within the relocated Runway 6 RPZ. The analysis found no incompatible land uses within the relocated Runway 24 RPZ beyond the two State Street relocation options.

Environmental impacts can be expected with the 360-foot extension to the northeast as regulated wetlands are found throughout the area east of State Street in the Runway 24 approach. As with Alternative 1, it is likely that both State Street alignment options would impact regulated wetlands. There are few environmental concerns or potential impacts associated with the extension of Runway 6 to southwest. Although two regulated wetlands and a constructed agricultural drainage ditch were previously delineated off the end of Runway 6, these resources are well outside the area of construction and would not be impacted by the 360-foot extension.

Commented [FJ(24]: Show wetlands on exhibit.

The primary advantage of Alternative 3 is that it provides 4,225 feet of usable runway length for turboprop and jet aircraft that currently operate at the Airport. This alternative would also realign Taxiway D so that it has a standard 90-degree intersection with the Runway 6/24 to address direct access issues.

Figure 2.3 Alternative 3 – Extend 360 Feet at Both Ends of Runway 6/24



Source: Mead & Hunt, Inc.

Disadvantages associated with Alternative 3 include the relocation of State Street around the approach end of Runway 24 and its associated RSA & ROFA surfaces. Like Alternative 1, this alternative would cause business and private property impacts where State Street connects to Ellsworth Road, likely causing land and commercial acquisitions. Also, community and road disruptions during construction are likely and wetland impacts with the realignment of State Street may also be expected.

Another disadvantage of Alternative 3 is that the ATCT will continue to have visibility concerns at the intersection of Taxiway A and connector Taxiway A1. Although the alignment of the intersection of Taxiway A1 with Runway 6/24 is improved so that it intersects at a right angle, the relocation of the intersection farther to the northeast would not allow air traffic controllers in the ATCT to view this area clearly, further complicating the current line-of-sight issue. According to FAA guidance, the entire movement area of the airfield should be observable from the ATCT. Under this alternative, FAA criterion would not be satisfied, and the existing condition would remain unresolved.

To implement this alternative, coordination with the FAA would be required to relocate the FAA owned REILs at the approach end of Runway 6 during final design and construction.

Alternative 3 is not considered a ~~prudent and feasible~~reasonable alternative because it fails to meet the project's purpose and need of addressing ATCT visibility issues associated with the intersection of Taxiway A and connector Taxiway A1. Although Alternative 3 provides adequate runway length for current and future users, it fails to provide line-of-sight for the entire movement area of the airfield.

Alternative 3 is the second most expensive of all the build options, with a preliminary cost estimate of $9.9 million. This alternative is approximately three times more expensive than Alternative 2.

2.7 ~~Summary of Impacts~~Comparison of Alternatives

Table 2.1 Summary of ~~Impacts~~ Alternatives Comparison provides an overview of ~~the anticipated impacts of~~ each build alternative in comparison to the purpose and need for the proposed project. ~~Potential impacts~~ Categories of interest are color coded either in "red" or "green" to aid in a visual understanding of the advantages and disadvantages of each alternative. Red indicates the alternative with the highest impact in a specific category while green indicates the alternative with the lowest impact in a particular category. The same criteria are used for each build alternative as to allow an "apples-to-apples" comparison to better evaluate the alternatives. The No-Build Alternative is shown for comparison purposes. For a detailed discussion of potential environmental impacts, see **Chapter 4.0 Environmental Consequences**.

2.8 ~~Selection of the Preferred Alternative~~Alternatives Considered but Discarded from Further Analysis

After a thorough analysis of the advantages and disadvantages of each alternative, the alternative that best meets the project's purpose and need, while minimizing impacts to the built and natural environment is Alternative 2 (see **Figure 2.2 Alternative 2 – Shift Runway 150 Feet Southwest and Extend 720 Feet at the Approach End of Runway 6** for an graphic representation of the proposed alternative).

Commented [LS(25]: Please note that alternatives are not based on economics; alternatives are selected based on the ability to best meet purpose and need while minimizing impacts. The statement as written is fine, but wanted to have some clarity on the assumption that alternatives are chosen based on economics, rather than purpose and need and impacts.

Commented [LS(26]: Rather than making the selection of the preferred without first going thru the environmental analysis I would suggest at end of chapter two discard the alternatives that do not meet purpose and need. This gives the general public an understanding of each alternative rather than showing that the proponent already made their decision on the preferred without the env analysis, so it is best to discard and move into the next chapter with the no build and build alternative (Alt. 2) since you have provided good justification why alternatives 1 and 3 do not meet purpose and need.

Commented [LS(27]: The environmental impacts analysis has not been discussed at this point, other than the wetlands and water resources in the table. Please revise so that you do not give impression that this alternatives comparison includes all environmental impact categories and that only these two categories are applicable.

Formatted: Highlight

Alternative 2 offers many advantages over the other alternatives. Alternative 2 provides 4,225 feet of needed runway length for turboprop and jet aircraft that currently operate at ARB. Alternative 2 would be built entirely within the existing property boundary without requiring the relocation of State Street or causing property or road construction impacts. Although there are regulated environmental resources in the project area, impacts to wetlands or other environmental resources are not anticipated with Alternative 2.

Shifting the runway 150 feet to the southwest eliminates the obstructed view from the ATCT so that air traffic controllers can view the entire movement area of Runway 6/24. Alternative 2 also corrects the geometry of the intersection of Taxiway A and Taxiway A1 with Runway 6/24 so that pilot visibility is maximized, and FAA design standards are met.

The 150-foot shift and runway extension to the southwest keeps the RPZ at the approach end of Runway 6 and Runway 24 entirely within existing ARB property, thus eliminating the need for land acquisition or easements to further control land uses within these areas.

Although Alternative 1 and Alternative 3 partially meet the project's purpose and need by providing adequate runway length to meet the needs of Airport operators, both alternatives fail to address ATCT visibility issues and will continue to have line of sight deficiencies when aircraft and ground vehicles are operating in the northeastern portion of Taxiway A.

Alternative 1 and Alternative 3 also require the relocation of State Street around the approach end of Runway 24 and its associated RSA and ROFA surfaces. Relocating State Street is likely to cause business and private property impacts, resulting in land and commercial acquisitions. Also, community, road, and wetland impacts during construction and realignment of State Street are likely. Lastly, Alternative 1 and Alternative 3 are significantly more expensive than Alternative 2.

Alternative 2 is considered the most ~~prudent and feasible~~ reasonable alternative when compared to the other alternatives. The recommendation that Alternative 2 be selected as the Preferred Alternative for this project has been accepted by the Airport and the Michigan Department of Transportation Office of Aeronautics. As a result, Alternative 2 is carried forward into the EA for additional analysis, public comment, and agency review.

Commented [LS(28]: Perhaps it would be best to state that the airport and MI DOT has recommended that Alternative 2 be carried forward into the EA for additional analysis rather that identifying as preferred without the environmental analysis (also since you are using feasible and prudent, it appears that there may be a 4f resource???)

Commented [FJ(29]: Since 163 is completed, this reference should state "Airport Sponsors proposed project" rather than preferred alternative. We can talk on next meeting as to how to reference and respond as one FAA.

Formatted: Highlight

For a detailed discussion of potential impacts of the Preferred Alternative, see **Chapter 4.0 Environmental Consequences**.

Table 2.1 Summary of ~~Impacts~~Alternatives Comparison					
Category	**Criteria**	**No-Build Alternative**	**Alternative 1**	**Alternative 2 (Preferred Alternative)**	**Alternative 3**
Meets Project Purpose and Need	Provides 4,225 ft of Runway Length for Current and Future Users	**No**	**Yes**	**Yes**	**Yes**
	Provides an Unobstructed View of Taxiway A and Airfield Movement Areas	**No**	**No**	**Yes**	**No**

Source: Mead & Hunt, Inc.

Commented [FJ(30]: Yes & no does not lead the reader to understand what the wetland impacts are for each alternative. There should be estimates included for each alternative for full disclosure. Also will there be tree impacts? If so a line for tree impacts as well. This will then provide information on potential endangered species impacts related to the Northern Long Eared Bat and Indiana Bat.

RESEARCH

Residential exposure to aircraft noise and hospital admissions for cardiovascular diseases: multi-airport retrospective study

Andrew W Correia *quantitative analyst*[1], Junenette L Peters *assistant professor*[2], Jonathan I Levy *professor*[2], Steven Melly *geographic information systems specialist*[3], Francesca Dominici *professor, associate dean of information technology*[4]

[1]NMR Group, Somerville, MA, USA ; [2]Department of Environmental Health, Boston University School of Public Health, Boston, MA, USA; [3]Department of Environmental Health, Harvard School of Public Health, Boston; [4]Department of Biostatistics, Harvard School of Public Health, Boston, MA 02115-6018, USA

Abstract

Objective To investigate whether exposure to aircraft noise increases the risk of hospitalization for cardiovascular diseases in older people (≥65 years) residing near airports.

Design Multi-airport retrospective study of approximately 6 million older people residing near airports in the United States. We superimposed contours of aircraft noise levels (in decibels, dB) for 89 airports for 2009 provided by the US Federal Aviation Administration on census block resolution population data to construct two exposure metrics applicable to zip code resolution health insurance data: population weighted noise within each zip code, and 90th centile of noise among populated census blocks within each zip code.

Setting 2218 zip codes surrounding 89 airports in the contiguous states.

Participants 6 027 363 people eligible to participate in the national medical insurance (Medicare) program (aged ≥65 years) residing near airports in 2009.

Main outcome measures Percentage increase in the hospitalization admission rate for cardiovascular disease associated with a 10 dB increase in aircraft noise, for each airport and on average across airports adjusted by individual level characteristics (age, sex, race), zip code level socioeconomic status and demographics, zip code level air pollution (fine particulate matter and ozone), and roadway density.

Results Averaged across all airports and using the 90th centile noise exposure metric, a zip code with 10 dB higher noise exposure had a 3.5% higher (95% confidence interval 0.2% to 7.0%) cardiovascular hospital admission rate, after controlling for covariates.

Conclusions Despite limitations related to potential misclassification of exposure, we found a statistically significant association between exposure to aircraft noise and risk of hospitalization for cardiovascular diseases among older people living near airports.

Introduction

Exposure to aircraft noise has been associated with physiological responses and psychological reactions,[1 2] such as sleep disturbances, sleep disordered breathing, nervousness, and annoyance.[2 3] However, the extent to which exposure to aircraft noise might increase the risk of adverse health outcomes is not well studied. Recent literature, primarily from one multicenter European study, has provided evidence of a relation between aircraft noise and hypertension outcomes, including incidence of hypertension,[4] self reported hypertension,[3] increased blood pressure,[5-8] and antihypertensive medication use.[1-11] These findings are supported by a broader literature, which evaluated the association between residential exposure to noise and cardiovascular disease and found substantial evidence for biological plausibility and positive associations between noise and hypertension, myocardial infarction, and ischemic heart disease.[12] Potential biological mechanisms may include induced release of stress hormones[13-15] and indirect effects on sympathetic activity, which is associated with adverse metabolic outcomes.[15-18]

However, few studies of the relation between aircraft noise and cardiovascular disease have been conducted to date,[1] in part because these studies have small numbers of airports and therefore do not have sufficient statistical power. One study in the Netherlands examined a single airport and had somewhat inconsistent findings, with an association between airport noise and hospital discharge for myocardial infarction in women but

Technical appendix

EXHIBIT 7, Page 1 of 11

not in men.[19] A large national scale study in Switzerland found evidence of an association between exposure to aircraft noise and myocardial infarction mortality.[20] To our knowledge, no study has been conducted to date that includes a large study population across multiple airports to estimate the association between exposure to aircraft noise and hospital admissions for cardiovascular outcomes. The rigorous estimation of this association requires a sufficiently large number of airports with large surrounding populations, and sufficient variation in the exposure to aircraft noise. We applied statistical methods (hierarchical Poisson regression models) to estimate the association between zip code level exposure to aircraft noise and zip code level hospital admission rate for cardiovascular disease for each airport, and also to estimate this association by combining information across all the airports. The hierarchical Poisson regression model allows us to adjust for potential confounders both at the individual level and at the zip code level, and to estimate airport specific and overall associations between exposure to aircraft noise and health outcomes accounting for the clustering of the zip code level observations by airport.

In this study we use the large and nationally representative US population of Medicare enrollees to evaluate the association between airport related noise and the risk of hospital admission for cardiovascular disease in the population aged 65 years or more residing near airports in the contiguous states. Understanding the link between aircraft noise and cardiovascular disease outcomes is important in characterizing the potential benefits of intervention strategies.[21]

Methods

We obtained the study population from Medicare billing claims for the year 2009. In the United States, unless affected by some specific chronic condition, only people aged 65 or more are eligible for the national insurance program, Medicare. Our study population (6 027 363 people aged ≥65 years enrolled in Medicare and residing in the 2218 zip codes close to the 89 airports) corresponds to approximately 15% of the entire US population of older people.

From the claims, we extracted individual level information regarding the date of hospitalization, length of hospital stay, the associated primary and secondary diagnostic and procedure codes (international classification of diseases), and the costs billed to Medicare. Additional individual level data included age, sex, race, and zip code of residence.

We examined five cause specific cardiovascular hospital admissions based on ICD-9 codes (international classification of diseases, 9th revision) for primary diagnosis: heart failure (ICD-9 428), heart rhythm disturbances (426 to 427), cerebrovascular events (430 to 438), ischemic heart disease (410 to 414, 429), and peripheral vascular disease (440 to 448). A variable for total cardiovascular disease admissions was calculated as the sum of hospital admissions for all these causes.

Noise exposure estimates

The US Federal Aviation Administration provided us with aircraft noise contours in decibels (dB) for 89 airports in the contiguous states. These noise levels were estimated at the centroid of each census block surrounding each of the 89 airports out to a minimum of 45 dB, where a census block is the smallest geographic entity for which population data are available in the US census. Noise contours were obtained using the Integrated Noise Model version 7.0a.[22] The noise descriptor used was day-night sound level (DNL), which adds a 10 dB “penalty” to night time (that is, 10 pm-7 am).[23] Medicare data provide residential information at the zip (postal) code level only. Zip codes are larger geographical areas that are comprised of census blocks (on average there are 168 census blocks per zip code). Therefore, we aggregated the noise exposure across census blocks to obtain an estimate of zip code level (technically, zip code tabulation area) exposure to noise. More specifically, we constructed the following two exposure metrics at zip code level: population weighted average noise (arithmetic mean) among the census blocks within each zip code, where each census block was weighted by the size of the population aged 65 or more obtained from the 2010 US census, and the 90th centile noise exposure among the census blocks within each zip code that contained at least one person aged 65 or more.

Several zip codes were intersected by the 45 dB noise contour at their respective airports, meaning they were comprised of census blocks with noise exposures of both 45 dB or more and less than 45 dB. To calculate our noise exposure metrics for these zip codes, we assigned a value of 45 dB to the census blocks outside the 45 dB contour, whereas census blocks inside the 45 dB contour were assigned their actual value, as estimated by the Integrated Noise Model. We considered only zip codes with census blocks within the 45 dB contour with people aged 65 or more that had Integrated Noise Model estimates when constructing the 90th centile noise exposure variable; for the 90th centile noise exposure there were 1928 such zip codes, with a combined population of 5 523 788 people aged 65 or more. Since Integrated Noise Model estimates were made at census block centroids, some zip codes were excluded because all census block centroids were outside the 45 dB contour.

In our preliminary analyses we developed other candidate noise metrics, including the variance of noise exposure across census blocks within each zip code and percentage of population above various noise thresholds, but focused on the population weighted average and 90th centile noise exposure given their distribution of values and interpretability. More details on the calculation of our two exposure metrics can be found in the technical appendix (see supplementary file).

Outcomes

For each zip code included in the analysis, we calculated the number of hospital admissions and the number of people at risk (Medicare enrollees) separately by two age groups (>75 or ≤75), sex, and race (white (non-Hispanic) or non-white). We conducted the analysis for hospital admissions for all cardiovascular diseases (our main analysis) and separately for cerebrovascular disease, ischemic heart disease, and heart failure. Preliminary analyses indicated that heart rhythm disturbances and peripheral vascular disease were too infrequent to analyze as stand alone outcomes.

Potential confounders

To adjust for the potential confounding effect of socioeconomic status, we extracted several zip code level variables from the 2000 US census. Extensive preliminary analyses led to the selection of percentage Hispanic and median household income as the two key variables that were included in the regression model. To adjust for the potential confounding effect of exposure to air pollution, we also calculated zip code level fine particulate matter ($PM_{2.5}$) and ozone concentrations for 1165 and 779 zip codes, respectively, out of the 2218 zip codes included in the analyses. Air pollution data were obtained from the US Environmental Protection Agency’s air quality system database, and we calculated zip code level averages by taking the average of the air pollution concentrations across all the monitors that fell in that zip code. In addition, as near-roadway air pollution and noise could both serve as confounders, we estimated zip code level road density. The technical appendix describes how road density was estimated (see supplementary file).

Statistical analysis

The dataset included hospital admission counts, number of people at risk, exposure to aircraft noise, and potential confounders for 2218 zip codes surrounding 89 airports. We used hierarchical Poisson regression models with airport specific random effects to estimate, for each airport and on average across airports, the percentage increase in the zip code level hospital admission rate associated with a 10 dB increase in the zip code level aircraft noise. We denote this percentage increase as the relative rate.

In more detail, the hierarchical Poisson regression model can be described in two stages. Firstly, we specified a Poisson regression model for zip code level data to estimate the relative rate as defined above for each airport adjusted by individual level variables (age, sex, and race) and zip code level potential confounders (socioeconomic status and air pollution). Secondly, we combined information across airports to estimate the relative rate on average across all airports. The model estimated airport specific relative rates and the average relative rate across all airports accounting for the clustering of the zip code level observations within each airport and for potential differences across airports in the association between noise and hospitalization rates. The technical appendix provides details on the mathematical formulation of the hierarchical Poisson regression model (see supplementary file).

To investigate the role of the potential confounding factors, we constructed three hierarchical Poisson regression models for each cardiovascular outcome and for each noise metric (population weighted average and 90th centile). Model 1 did not include any zip code level confounders and only controlled for individual level variables (age, sex, and race). Model 2 additionally controlled for zip code level socioeconomic status and demographic variables (median household income and percentage Hispanic). Model 3 additionally controlled for zip code level exposure to air pollution (fine particulate matter and ozone); model 3 was fitted to a substantially smaller dataset of 779 zip codes rather than the 2218 zip codes used for models 1 and 2, because of the limited availability of air pollution data. In secondary analyses of models 2 and 3 we evaluated the potential confounding effect of zip code level road density (a proxy for road noise and near-road air pollution).

Threshold analysis

We conducted additional analyses to quantify the evidence of a potential non-linearity in the association between exposure to aircraft noise and hospital admission rate for cardiovascular disease. We used total hospitalizations for cardiovascular disease as the outcome and the 90th centile noise exposure metric. In the hierarchical models, we replaced the aircraft noise exposure variable (originally defined as a continuous variable) by a categorical variable indicating low, medium, or high exposure to aircraft noise. A zip code was designated as low exposure for noise levels of 50 dB or less (47% of the study population), medium exposure for noise levels greater than 50 dB but 55 dB or less (30%), and high exposure for noise levels greater than 55 dB (23%). Under this model we could estimate three different percentage increases in hospital admission rates for cardiovascular disease corresponding to: medium versus high exposure, low versus high exposure, and low versus medium exposure. Categorizing the exposure in this way, we could detect evidence of a threshold effect if, for example, we found no evidence of an increase in the cardiovascular disease hospitalization rate when noise increases from low to medium, but statistically significant evidence of an increase in the cardiovascular disease hospitalization rate when noise increases from medium to high. Such a scenario would suggest that any relation between noise exposure and cardiovascular disease hospitalizations only occurs for noise exposures above 55 dB. All statistical analyses were performed using R version 2.15.2. The technical appendix provides more details regarding statistical methods (see supplementary file).[24 25]

Population attributable fraction

To facilitate the interpretation of our findings, we estimated the population attributable fraction for aircraft noise as well as for fine particulate matter and ozone. The population attributable fraction can be interpreted as the percentage reduction in hospitalizations for cardiovascular disease that would occur if each of these risk factors was reduced to a level that represents theoretical minimum risk, termed the counterfactual exposure distribution.[26] For aircraft noise, we used the 90th centile exposure metric, and we considered the counterfactual level of exposure for all zip codes as 45 dB (the lowest level of exposure evaluated in our study). Similarly, for both fine particulate matter and ozone we used the minimum concentration within our domain as the counterfactual level of exposure (4.8 $\mu g/m^3$ and 17.6 ppb, respectively). All relative risk estimates were taken from an expanded version of model 3, which incorporated additional zip code level covariates that could potentially confound air pollution effects but had no influence on the association between aircraft noise and hospitalization for cardiovascular disease. For each risk factor we estimated the population attributable fraction across all zip codes that had exposure data for that risk factor. To ensure that the population attributable fraction estimates were comparable to one another, given air pollution data from only a subset of zip codes, we also calculated the population attributable fraction for noise for the subset of zip codes with data on air pollution. More detail about the calculation is available in the technical appendix (see supplementary file).

Results

Overall, there were 2218 zip codes (779 with both fine particulate matter and ozone data) and 6 027 363 Medicare enrollees residing within the 45 dB contour level of the 89 airports. The number of zip codes (Medicare enrollees) surrounding each airport ranged from seven (n=8556) to 107 (n=482 200). The table⇓ summarizes the population characteristics, and figure 1⇓ provides a map presenting the 89 airports displayed by size of the population aged 65 or more within the 45 dB contour level.

Figure 2⇓ shows the estimated relative rates for cardiovascular disease hospitalizations averaged across all airports for both the population weighted noise exposure and the 90th centile of noise exposure. For the 90th centile of noise exposure variable, controlling for age, sex, and race, an increase of 10 dB was associated with an increase of 2.9% (95% confidence interval 0.8% to 5.0%) in hospital admission rate (model 1). In model 2, which additionally controls for zip code level socioeconomic status and demographic variables, the estimated relative rate was only marginally significant (1.6%, 95% confidence interval −0.2% to 3.5%). In model 3, adding pollution variables to model

2, an increase in the 90th centile of noise of 10 dB was associated with an increase of 3.5% (95% confidence interval 0.2% to 7.0%) in the relative rate of having a cardiovascular disease hospitalization. Models 1 to 3, when fitted to only the 779 zip codes with both fine particulate matter and ozone data, yielded consistently positive and statistically significant estimates of the relative rate of cardiovascular disease hospitalizations associated with a 10 dB increase in the 90th centile of noise (fig 2). Figure 3⇓ displays the airport specific and aggregated relative rates (for model 3) of having a cardiovascular disease hospitalization per 10 dB increase in the 90th centile of noise exposure. In secondary analyses (data not shown), we observed that the relation of noise to cardiovascular disease hospitalizations was almost entirely attributed to within airport and across zip code variations in noise exposure rather than to variations between airports. Indeed, the average within airport standard deviation of our 90th centile noise exposure was 4.7 dB, whereas the average between airport standard deviation of the 90th centile noise exposure was only 1.7 dB, indicating that most of the information used to estimate the noise-cardiovascular disease relation in our models was from variability in exposure within airports, rather than from variability in exposure between airports.

For population weighted noise exposure, there was an estimated 6.9% increase (95% confidence interval 2.4% to 11.6%) in the cardiovascular disease hospital admission rate associated with a 10 dB increase in noise in model 1; however, after controlling for socioeconomic status, demographic, and pollution variables (models 2 and 3), this association was no longer statistically significant. Figure 4⇓ shows the airport specific estimated associations for model 3 for population weighted noise. The standard errors of the airport specific estimates were consistently larger than those estimated in models using the 90th centile of noise exposure, due potentially in part to the relatively limited variability of population weighted noise across zip codes within the dataset (see table). Because of this larger standard error in models using the population weighted noise exposure, we focused subsequent analyses on the 90th centile of noise exposure.

Considering subcategories of cardiovascular disease outcomes, we observed generally consistent patterns among models. For example, in model 1, an increase in the 90th centile of noise of 10 dB was associated with cerebrovascular disease and heart failure, with a marginal association for ischemic heart disease. Relative rate estimates were similar across outcomes (fig 5⇓). For model 2, relative rate estimates for all three outcomes declined in magnitude and lost statistical significance. Inclusion of pollution variables (model 3) led to stable or increased relative rate estimates for all three outcomes, relative to model 2. These estimates lacked statistical significance other than for ischemic heart disease but were similar in magnitude to the estimates from model 1. For the population weighted noise exposure, a similar pattern was observed (fig 5).

We found that associations were not sensitive to adjustment for our proxy for road noise and near-road air pollution (road density). In models 2 and 3, the overall estimates per 10 dB increase in the 90th centile of noise without road density were 1.6% (95% confidence interval −0.2% to 3.5%) and 3.5% (0.2% to 7.0%), respectively, and with road density the estimates were 1.6% (−0.4% to 3.5%) and 3.4% (0.3% to 6.7%), respectively.

Figure 6⇓ summarizes the results using the categorized 90th centile noise exposure variable (low, medium, or high). In model 3—controlling for socioeconomic status, demographic, and pollution variables—we found statistically significant evidence of an increase in the hospital admission rate for cardiovascular disease when comparing high versus medium exposure and high versus low exposure, but we did not find statistically significant evidence of an increase when comparing medium versus low exposure. This indicates lack of an association between the 90th centile exposure to aircraft noise and hospital admission rate for cardiovascular disease for noise levels below 55 dB but evidence of an association for noise levels higher than 55 dB.

From the estimation of the population attributable fraction we found that, in total, 2.3% of hospitalizations for cardiovascular disease in our Medicare cohort were attributable to aircraft noise. Twenty three per cent of our Medicare cohort was exposed to greater than 55 dB using the 90th centile exposure metric, and this population contributed half of the attributable hospitalizations. In comparison, across the zip codes with air pollution data, 6.8% of hospitalizations for cardiovascular disease were attributable to fine particulate matter and 4.2% to ozone. The population attributable fraction for noise was similar in the subset of zip codes with air pollution data (2.2%).

Discussion

We estimated the association between residential exposure to aircraft noise and hospitalization rates for cardiovascular disease in the largest population of older people (≥65 years) in the United States studied to date. In models only controlling for individual demographics, we found that this association was positive and statistically significant using both of our noise exposure metrics. The results were attenuated after additionally controlling for area level socioeconomic status and demographic factors. However, the positive association generally persisted, with the most adjusted model accounting for individual level and zip code level variables as well as regional air pollution—particularly for the 90th centile of noise exposure variable, which had greater variability across zip codes than the population weighted average, and correspondingly had greater statistical significance. Positive associations were also observed for individual cardiovascular hospitalization outcomes, but statistical power was reduced.

Comparison with other studies

Our findings add to previous literature in several key ways. Firstly, we investigated the noise-cardiovascular hospitalization relation across gradients of airport noise exposure levels for the largest number of airports and population of older people studied to date. We used administrative data capturing the majority of older US adults, who represent an age group at greater risk for cardiovascular disease. We thus had a large number of events, increasing our power to detect relations. We used hierarchical Poisson regression models to estimate airport specific associations while utilizing information from each airport for a pooled estimate. Secondly, we evaluated the relation of noise with cardiovascular hospitalization as the outcome, which, to our knowledge, has been rarely considered in previous noise studies. An ecological study of 62 municipalities around an airport in Amsterdam found no clustering of cardiovascular hospitalizations in areas close to the airport,[27 28] but we improve on this study by assessing the relation for individual at risk people and by estimating the whole exposure-response relation. Thirdly, our study provides evidence within the United States, where the housing stock and other factors may differ from the European populations generally studied in the past. US studies have been more limited and have not yielded interpretable evidence. For example, the only major US study to date that investigated the relation between aircraft noise and mortality[29] was conducted more than 30 years ago, focused on a single airport, and was critiqued for inadequately controlling for age/sex/race, and other analytical flaws.[30] Fourthly, we accounted for the potential confounding of regional air pollution and near-road air pollution/noise.

The estimated associations of similar magnitude across several cardiovascular disease specific outcomes are broadly consistent with the literature. For example, in areas with more aircraft noise, more people were receiving medical treatment for heart trouble and had a "pathological heart shape."[31] A 2009 review of epidemiological studies found sufficient evidence of positive relations between aircraft noise and high blood pressure and use of cardiovascular medication.[32] One study included in this review investigated the relation between aircraft noise and incidence of hypertension and found a positive association, particularly in older people.[33] Hypertension is not typically a primary reason for hospital admission, so it was not specifically included in our analyses, but hypertension is associated with multiple cardiovascular sequelae that would contribute to hospitalizations.

Our study suggests that although an exposure-response relation exists between noise and cardiovascular admission rates, there may also be a threshold for the effect of noise exposure on cardiovascular disease hospitalizations. Results from our models using a categorized exposure variable showed consistent statistically significant associations in only the highest exposure group (>55 dB). These findings are broadly consistent with previous literature suggesting the possibility of a threshold effect for the aircraft noise-cardiovascular disease relation. In a categorical analysis, Huss and colleagues[20] observed significant mortality from myocardial infarction with aircraft noise only in the highest group of 60 dB (A weighted) or more. Other studies found associations with hypertension outcomes with levels 50 dB (A weighted) or more,[4 33] but did not see results with categories further divided above 50 dB (A weighted) likely due to small numbers in higher categories.[4] It should be noted that our noise exposure metrics were calculated differently from those in prior studies, given zip code level residential resolution, so the noise level at which effects are seen cannot be directly compared.

We did not find statistically significant evidence of heterogeneity in the relation between aircraft noise and cardiovascular hospitalization across airports. In addition we found that evidence of an association between aircraft noise and cardiovascular hospitalization was mainly attributable to variation in noise exposure within airports and not differences between airports. As proposed elsewhere,[11] any observed heterogeneity may reflect differences across the country in sound transmission from outdoors to indoors (where most exposure would be anticipated to occur). This could include structural attributes of the housing stock, frequency of open windows, or degree of soundproofing. Heterogeneity may also reflect differences in the type of aircraft and the frequency of over-flights between airports, although this would be incorporated to some extent in Integrated Noise Model inputs and outputs.

In addition, although aircraft related noise has a different profile from that of traffic related noise, our findings are consistent with the traffic noise-cardiovascular disease health literature. For example, in models controlling for individual characteristics, zip code level socioeconomic status and demographics, and air pollution, we found the strongest association (positive and statistically significant) with hospitalizations for ischemic heart disease, consistent with conclusions of an expert report regarding likely mechanisms of noise related health effects.[12] Our findings were also consistent with studies looking jointly at noise and air pollution. For example, Beelen and colleagues[34] found excess cardiovascular mortality in the highest category of road traffic noise, which was reduced slightly after controlling for air pollution. Huss and colleagues[17] found that the association between aircraft noise and mortality from myocardial infarction was not attenuated with adjustment for air pollution. De Kluizenaar and colleagues[35] found that after controlling for particulate matter (PM_{10}), the relation between road traffic noise and hypertension became marginally significant. We found that controlling for air pollution and road traffic density did not attenuate the relative rate for both of the aircraft noise exposure metrics. It is worth noting that air pollution is less correlated with aircraft noise than it is with road traffic noise.[20]

Limitations of this study

Our analysis has limitations. Although Medicare data covers nearly the entire US older population, this database was developed for administrative purposes and has been shown to be subject to misclassification[36 37] and geographic variability in evaluation and management.[38 39] We only used primary diagnosis, which should reduce misclassification of outcomes,[40] and our analyses of combined cardiovascular disease outcomes are unlikely to have significant misclassification.

Other limitations of the Medicare data include limited individual data on risk factors. For example, we were not able to control for smoking and diet, strong risk factors for cardiovascular disease. These variables would only confound the association between aircraft noise and hospitalization for cardiovascular disease if there were significant correlations between aircraft noise exposures and these risk factors. Noise contours display fairly sharp gradients and skew as a function of prevailing wind directions, given runway orientation, and arrival and departure patterns, which may limit spatial confounding. It is possible that socioeconomically patterned risk factors such as smoking are spatially correlated with aircraft noise, as property values have been found to relate to noise levels.[41] However, property value is not simply tied to aircraft noise levels but is affected by a complex interplay of several factors (for examples, amenities).[42] Our estimates were generally robust to socioeconomic status covariates at area level, but we lacked the individual level addresses and socioeconomic status characteristics to formally address this question. In addition, our zip code level socioeconomic status and demographic variables were taken from census 2000 data because only limited socioeconomic status information from census 2010 was available at the zip code level at the time of our analysis. We thus assumed that patterns of zip code level socioeconomic status remained similar over that time. More generally, the availability of only zip code level address information can lead to exposure misclassification. Noise gradients are substantial at close proximity to airports, and we were unable to differentiate among individuals' noise exposure within zip codes. However, the use of a study population closely aligned with census data (given near universal enrollment of older people in Medicare) allowed us to reasonably estimate a representative zip code resolution population exposure, with error most likely to be Berksonian with unbiased regression coefficients and inflated standard errors. There remains the possibility of downward bias in our estimates due to aggregation effects, but bias has been shown to be limited when within area variance is small relative to between area variance.[43 44] Between zip code variance in noise is larger than within zip code variance, especially for the 90th centile noise exposure, so we would not anticipate substantial bias. However, there is some chance for attenuated effect estimates for the population weighted noise

EXHIBIT 7, Page 5 of 11

exposure because of comparatively smaller between zip code variance in this exposure metric.

Using the Integrated Noise Model to predict noise exposure also has limitations. The model uses average annual input conditions. Therefore, values may lack precision because certain local acoustical variables, such as humidity effects, ground absorption, individual aircraft directivity patterns, and sound diffraction around terrain or buildings, are not averaged or may not be explicitly modeled.[22] That said, the Integrated Noise Model is well established internationally[4] and is the required noise assessment tool in the United States for airport noise compatibility planning and environmental assessments and impact statements.[22] Each of our derived exposure metrics had its own inherent limitations, with the population weighted average potentially reducing the contrast between zip codes, and the 90th centile of noise exposure not capturing the exposure profile of the entire zip code. Our data were not separated by time of day, so we were not able to analyze the effect of night time noise. This is particularly relevant as recent studies found associations of night time noise on cardiovascular related outcomes[5 9] suggesting that sleep interference may mediate the effect of noise on cardiovascular health. However, the Integrated Noise Model outputs did up-weight night time noise, partially accounting for this phenomenon.

Conclusions and future research

We found that aircraft noise, particularly characterized by the 90th centile of noise exposure among census blocks within zip codes, is statistically significantly associated with higher relative rate of hospitalization for cardiovascular disease among older people residing near airports. This relation remained after controlling for individual data, zip code level socioeconomic status and demographics, air pollution, and roadway proximity variables. Our results provide evidence of a statistically significant association between exposure to aircraft noise and cardiovascular health, particularly at higher exposure levels. Further research should refine these associations and strengthen causal interpretation by investigating modifying factors at the airport or individual level.

What is already known on this topic

Noise has been associated with hypertension, myocardial infarction, and ischemic heart disease

Aircraft noise in particular has been associated with several hypertension outcomes

Few studies, however, have investigated the relation of aircraft noise to cardiovascular disease, in part because studies surrounding a small number of airports are not typically adequately powered

What this study adds

Long term exposure to aircraft noise is positively associated with hospitalization for cardiovascular disease

The association between aircraft noise and hospitalization for cardiovascular disease is not confounded by air pollution, road density, or area level socioeconomic status

There may be a threshold for the association between aircraft noise and hospitalization for cardiovascular disease

Table

Table 1| Distribution of zip code level exposure for 2218 zip codes and risk factor data for about six million national insurance plan (servicing those aged ≥65 years) enrollees residing near airports in United States, 2009. Values are percentages unless stated otherwise

Characteristics	Median (interquartile range)
>75 years old (among population aged ≥65)	42.7 (37.3-47.7)
Black ethnicity	5.5 (1.8-20.2)
Hispanic	6.2 (2.1-19.8)
Median household income ($000s)	45.1 (34.9-57.3)
Graduated high school	82.9 (72.8-90.0)
Fine particulate matter ($PM_{2.5}$; annual average, μg/m^3)*	10.2 (9.1-11.3)
Ozone (annual average, ppb)†	25 (22-28)
Population weighted noise (dB, DNL)	45.9 (45.1-48.6)
90th centile of noise among populated census blocks (dB, DNL)	50.3 (47.5-54.5)
Hospital admission rate per 100 000 population:	
All cardiovascular	6288.9 (5064.7-7697.6)
Cerebrovascular events (stroke)	1343.3 (1092.5-1652.2)
Ischemic heart disease	1568.2 (1173.7-1987.8)
Heart failure	1576.4 (1125.2-2142.9)
Heart rhythm disturbances	1222.8 (932.1-1531.2)
Peripheral vascular disease	421.9 (280.3-582.7)

DNL=day-night sound level.
*1165 zip codes with data for $PM_{2.5}$.
†779 zip codes with data for ozone.

Figures

Fig 1 Map of 89 airports in contiguous states included in analysis. Size of circles is proportional to size of population aged 65 or more residing within 45 dB contour lines surrounding each airport

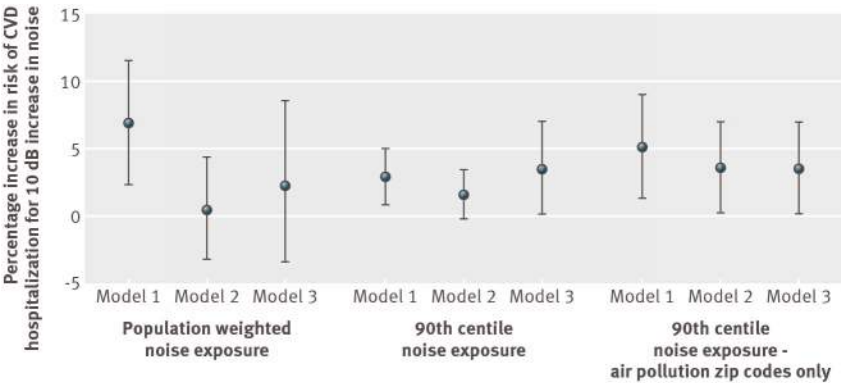

Fig 2 Overall estimates (averaged across 89 airports) of percentage increase in hospital admission rate for cardiovascular disease (CVD) associated with 10 dB (day-night sound level) increase in both exposure variables (population weighted noise exposure and 90th centile noise exposure) for each of the models. Model 1 controls for individual demographics (age, sex, and race); model 2 additionally controls for zip code level socioeconomic status and demographics (% Hispanic and median household income); and model 3 adds to model 2 by also controlling for annual average fine particulate matter and ozone levels. Panel 3 shows models 1 to 3 fitted to only the 779 zip codes with both air pollution variables

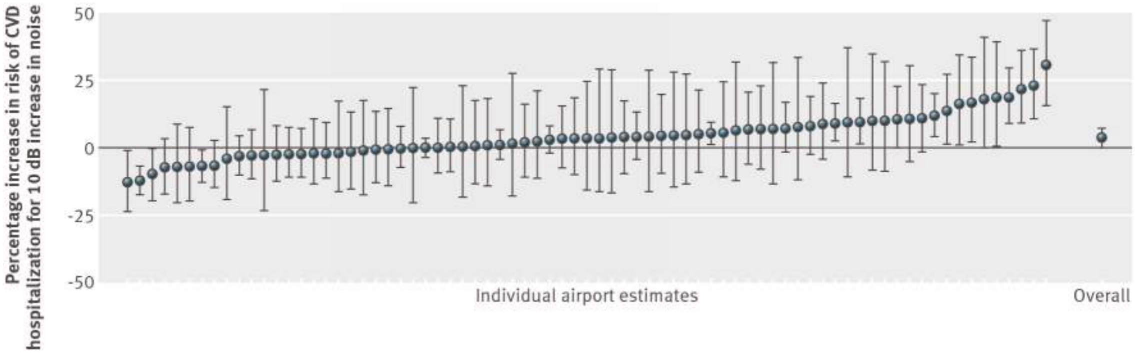

Fig 3 Airport specific and overall estimates of percentage increase in hospital admission rate for cardiovascular disease (CVD) associated with 10 dB (day-night sound level) increase in 90th centile noise exposure among census blocks within zip codes. Model controls for individual demographics (age, sex, and race), zip code level socioeconomic status and demographics (% Hispanic and median household income), and annual average fine particulate matter and ozone levels (model 3). Airport specific estimates are arranged from lowest to highest values

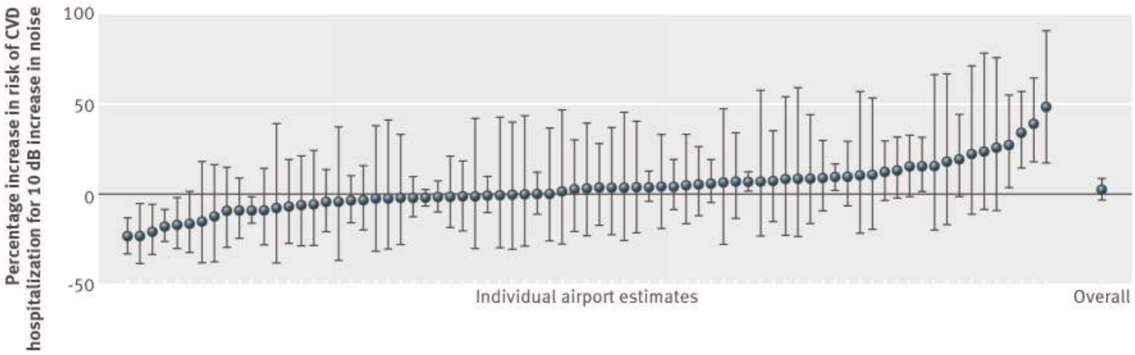

Fig 4 Airport specific and overall estimates of percentage increase in hospital admission rate for cardiovascular disease (CVD) associated with 10 dB (day-night sound level) increase in the population weighted noise exposure. This model controls for individual demographics (age, sex, and race), zip code level socioeconomic status and demographics (% Hispanic and median household income), and annual average fine particulate matter and ozone levels (model 3). Airport specific estimates are arranged from lowest to highest values

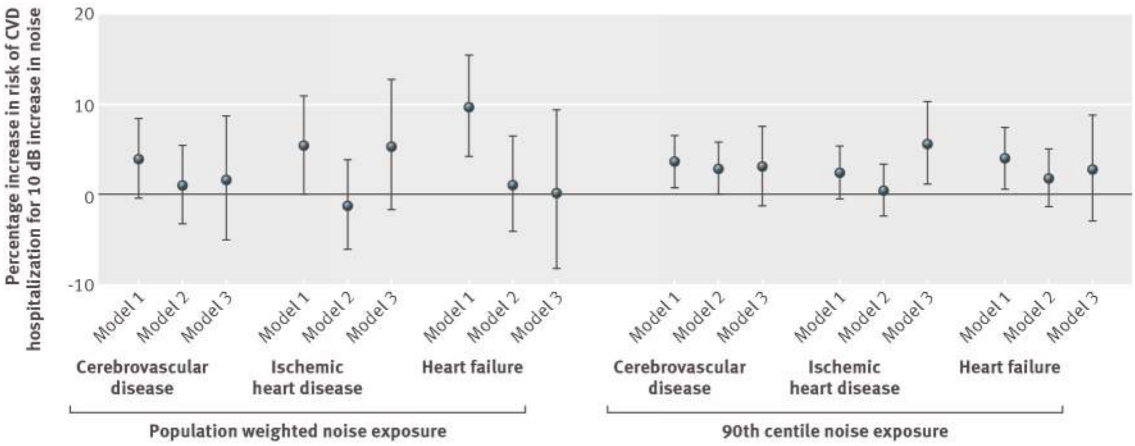

Fig 5 Overall estimates of percentage increase in hospital admission rate for specific cardiovascular diseases (CVD) associated with 10 dB (day-night sound level) increase in noise exposure. Results are reported for cerebrovascular disease (stroke), ischemic heart disease, and heart failure, and for both exposure variables (population weighted noise exposure and 90th centile noise exposure) for each of the three models. Model 1 controls for individual demographics (age, sex, and race); model 2 additionally controls for zip code level socioeconomic status and demographics (% Hispanic and median household income); and model 3 adds to model 2 by also controlling for annual average fine particulate matter and ozone

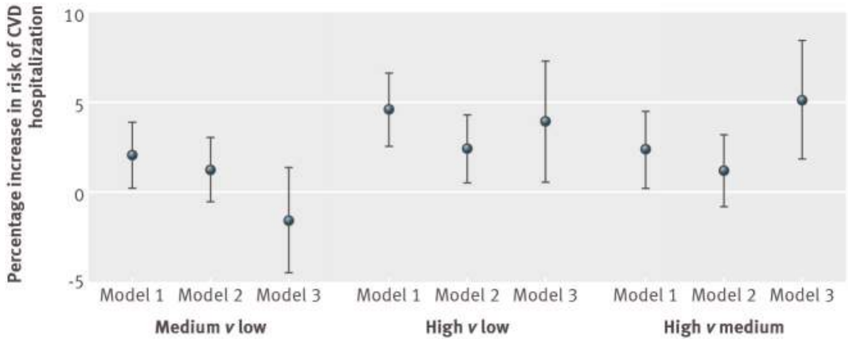

Fig 6 Estimated relative rates of cardiovascular disease (CVD) hospitalization from models using categorized 90th centile of noise exposure. Low noise indicates <50 dB, medium noise indicates 50-55 dB, and high noise indicates >55 dB. Model 1 controls for individual demographics (age, sex, and race), model 2 additionally controls for zip code level socioeconomic status and demographics (% Hispanic and median household income), and model 3 adds to model 2 by also controlling for fine particulate matter and ozone levels

Abstract

Objective To investigate the association of aircraft noise with risk of stroke, coronary heart disease, and cardiovascular disease in the general population.

Design Small area study.

Setting 12 London boroughs and nine districts west of London exposed to aircraft noise related to Heathrow airport in London.

Population About 3.6 million residents living near Heathrow airport. Risks for hospital admissions were assessed in 12 110 census output areas (average population about 300 inhabitants) and risks for mortality in 2378 super output areas (about 1500 inhabitants).

Main outcome measures Risk of hospital admissions for, and mortality from, stroke, coronary heart disease, and cardiovascular disease, 2001-05.

Results Hospital admissions showed statistically significant linear trends (P<0.001 to P<0.05) of increasing risk with higher levels of both daytime (average A weighted equivalent noise 7 am to 11 pm, $L_{Aeq,16h}$) and night time (11 pm to 7 am, L_{night}) aircraft noise. When areas experiencing the highest levels of daytime aircraft noise were compared with those experiencing the lowest levels (>63 dB *v* ≤51 dB), the relative risk of hospital admissions for stroke was 1.24 (95% confidence interval 1.08 to 1.43), for coronary heart disease was 1.21 (1.12 to 1.31), and for cardiovascular disease was 1.14 (1.08 to 1.20) adjusted for age, sex, ethnicity, deprivation, and a smoking proxy (lung cancer mortality) using a Poisson regression model including a random effect term to account for residual heterogeneity. Corresponding relative risks for mortality were of similar magnitude, although with wider confidence limits. Admissions for coronary heart disease and cardiovascular disease were particularly affected by adjustment for South Asian ethnicity, which needs to be considered in interpretation. All results were robust to adjustment for particulate matter (PM_{10}) air pollution, and road traffic noise, possible for London boroughs (population about 2.6 million). We could not distinguish between the effects of daytime or night time noise as these measures were highly correlated.

Conclusion High levels of aircraft noise were associated with increased risks of stroke, coronary heart disease, and cardiovascular disease for both hospital admissions and mortality in areas near Heathrow airport in London. As well as the possibility of causal associations, alternative explanations such as residual confounding and potential for ecological bias should be considered.

Introduction

Although the literature on population annoyance associated with aircraft noise is extensive,[1 2] little research has been conducted on the potential effects of aircraft noise on cardiovascular health.[2] Most studies of the health effects associated with aircraft noise have focused on blood pressure and the risk of hypertension.[3-8] The few reports of aircraft noise and risk of stroke, coronary heart disease, or cardiovascular disease are inconsistent,[9-12] partly reflecting reduced statistical power

Supplementary information

because of the small proportion of the population exposed to high aircraft noise levels.[10 11]

Noise levels show a graded, direct relation with prevalence of annoyance. This is greater for aircraft noise than for other environmental noise sources—that is, road traffic or rail[1]; community annoyance due specifically to aircraft noise seems to have increased in the past 30 years.[13] Noise is associated with activation of the sympathetic nervous system.[14] In animal models, chronic exposure to noise leads to increases in blood pressure,[15 16] and in humans noradrenaline (norepinephrine) levels,[17] whereas acute exposure to non-habitual loud noise increases adrenaline (epinephrine) levels.[17] Experimental studies of humans acutely exposed to noise at very high level also show increases in blood pressure[18] and heart rate.[19]

Heathrow airport, situated in a densely populated area in west London, is one of the busiest airports in the world. Reports have shown an association between aircraft noise, especially at night, and hypertension,[3] acute increases in blood pressure,[7] and self reported cardiovascular disease[12] in the population living near airports, including Heathrow. We investigated the risks of stroke, coronary heart disease, and cardiovascular disease hospital admissions and mortality in areas exposed to aircraft noise near Heathrow airport.

Methods

We carried out analyses comparing rates of hospital admissions for cardiovascular disease and mortality in neighbourhoods (small areas) exposed to different levels of aircraft noise related to Heathrow airport. We used a standard noise metric, the A weighted equivalent (Aeq) sound pressure level (L), denoted as L_{Aeq}. The human ear is more sensitive to some frequencies than others. The L_{Aeq} devalues lower frequencies compared with medium and higher frequencies,[20] and uses a set of mathematical curves to adjust the sound pressure level to the relative loudness perceived by human hearing. We defined daytime noise ($L_{Aeq,16h}$) as the average A weighted equivalent noise from 7 am to 11 pm and night time noise (L_{night}) from 11 pm to 7 am.

Study area and population

The study area comprised 12 London boroughs and nine districts west of London exposed to aircraft noise related to Heathrow airport, defined as being partly or wholly within the 2001 50 dB noise contour for Heathrow aircraft during the daytime ($L_{Aeq,16h}$) supplied by the Civil Aviation Authority (fig 1⇓). Additionally, we had confounder data for particulate air pollution and road traffic noise for the 12 London boroughs (data for districts outside London were not readily comparable with the data available for London).

We defined neighbourhoods (small areas) by using the national census geographical units, which are census output areas and super output areas. The study area comprised 12 110 census output areas (average 297 inhabitants, area 0.13 km^2) and 2378 super output areas (1510 inhabitants, area 0.65 km^2). We used the census output area as the unit of analysis for hospital admissions and the super output area, an aggregate of on average five census output areas, for mortality as the numbers of deaths were insufficient for meaningful analyses at census output area level. We used Office for National Statistics annual mid-year population estimates by age and sex for 2001-05 at London borough or district level, which we then disaggregated to census output areas and super output areas using the UK 2001 census age-sex distribution.

Aircraft noise data

From the Civil Aviation Authority we obtained aircraft noise data related to Heathrow airport for 2001 on 10 m × 10 m grids. The noise data had been modelled using the UK Civil Aircraft Noise Contour Model ANCON, which uses information on flight paths of arriving and departing aircraft along with factors such as height, speed, and engine power to derive noise at ground level.[21]

We calculated population weighted annual average noise levels for daytime and night time aircraft noise for census output areas and super output areas. This was done because the noise grid was smaller than the area of the census output area or super output areas and populations are not evenly distributed (for example, a census output area has on average 125 addresses and six postcodes that may cluster to one or other side of the census output area) so a simple area averaging would not accurately represent population exposures (see supplementary appendix).

Health data

We extracted post coded data on hospital admissions (main reason for admission, first episode of stay in a given year) and deaths (by underlying cause) for the study area, 2001-05, from Office for National Statistics and Department of Health data held by the UK Small Area Health Statistics Unit at Imperial College London. Data were obtained for stroke (ICD-10 codes I61, I63-I64, international classification of diseases, 10th revision), coronary heart disease (ICD-10 I20-I25), and cardiovascular disease (ICD-10 Chapter I) and then linked these by postcode (average 23 households) to census output area and super output area.

Data on potential confounders

We included ethnicity, deprivation, and a smoking proxy at census output area and super output area level as potential confounders. Area level ethnic composition and deprivation from the 2001 census were obtained from the Office for National Statistics. For the two major ethnic groups in London, we categorised areas by South Asian ethnicity (census term "Asian or Asian British," for which we included only "Indian," "Pakistani," and "Bangladeshi") and black ethnicity (census term "Black or Black British," which includes "Black Caribbean," "Black African," and "Other Black"). We used the following cut points: the national average (%) for England and Wales at census output area level (4% for South Asian, 2% for black ethnicity), double the national average (8%, 4%), and 50% South Asian or black ethnicity—areas where these comprised the majority ethnic group. This gave us four categories for each ethnicity, where the reference categories were less than or equal to the national average (%) for that ethnic group (≤4% for South Asian and ≤2% for black ethnicity). The deprivation score used was Carstairs index,[22] categorised in fifths. As a proxy measure for area level smoking we used smoothed lung cancer mortality (ICD-10 codes C33-C34) relative risk estimates, 2005, for census output areas and super output areas,[23] since data on individual smoking or smoking prevalence were not available.

For the 12 London boroughs within the study area we also obtained data on air pollution and daytime road noise. For air pollution, the Environmental Research Group at King's College London provided estimates of annual mean particulate matter of 10 microns or less (PM_{10}) at spatial resolution of 20 m × 20 m for 2001, using dispersion modeling as detailed in the London Emissions Toolkit and London Air Pollution Toolkit.[24] We obtained data on daily average road traffic noise for 2001 from the Department for Environment, Food and Rural Affairs (Defra), expressed in continuous A weighted equivalent sound pressure levels ($L_{Aeq,16h,road}$) on 10 m × 10 m grids at 1 dB resolution between ≥50 dB and ≤75 dB. Road traffic noise data (major roads) had been generated to comply with the European Noise Directive 2002/49/EC (http://ec.europa.eu/environment/noise/directive.htm) and modeled using the calculation of road traffic noise method at a height of 4 m above ground using characteristics of the road network.[25] We linked the air pollution and road noise data to census output area and super output area using population weighting (see supplementary appendix).

Statistical analyses

Correlations between aircraft noise and potential confounders were assessed using Goodman Kruskal tau rank correlation coefficients.

For the entire study area we carried out a small area analysis of aircraft noise and the three cardiovascular outcomes, adjusted for potential confounders at area level (census output area or super output area): age, sex, South Asian and black ethnicity, deprivation, and smoking proxy (lung cancer mortality risk). We conducted a sensitivity analysis for the 12 London boroughs (London area) additionally including particulate air pollution (PM_{10}) and road noise as potential confounders.

We grouped daytime aircraft noise and road noise into six categories from ≤51 to >63 dB in increments of 3 dB, which represents a doubling in sound intensity that is just perceptible as a change in loudness to the human ear. For aircraft noise, 57 dB L_{Aeq} is taken as the point at which noticeable community annoyance starts to occur[26 27]; the Civil Aviation Authority attempts to minimise areas exposed to this level of noise or higher, measured as the daytime $L_{Aeq,16h}$ over a 92 daytime summer period.[27] Our $L_{Aeq,16h}$ aircraft noise categories include a 57 dB cut point, although we use an annual not summertime average (fig 1). Night time aircraft noise affected fewer areas (fig 1), and 5 dB categories (≤50, >50-55, and >55 dB) were used.

To aid comparisons between daytime and night time aircraft noise, we also ran daytime analyses using the same 5 dB categories. The correlation between daytime and night time aircraft noise categories was almost perfect (τ ≥0.98, see supplementary table 2) so we did not include these together in the statistical models, but analysed them separately.

To allow for small numbers and unstable rates of hospital admissions and mortality we used random effects models to produce smoothed relative risk maps. To examine the effects of noise we fitted Poisson regression models with an additional random effect term to account for over-dispersion and residual heterogeneity, using the R software (www.r-project.org/) and tested for linear trend across noise categories using the median noise value for each category.

Results

Figure 1 shows the study area; the population (2001 census) was 3.6 million. During 2001-05, 189 226 first episodes of hospital stay in a given year for cardiovascular disease (16 983 stroke, 64 448 coronary heart disease) and 48 347 cardiovascular disease related deaths (9803 stroke, 22 613 coronary heart disease) occurred in the study area (table⇓). Supplementary figures 1 and 2 show the maps of hospital admissions at census output area level and mortality at super output area level, respectively. Only 2% or fewer of the study population lived in areas exposed to the highest category of daytime (>63 dB) or night time (>55 dB) aircraft noise (see supplementary table 1).

The area affected by night time noise was less extensive than that for daytime noise (fig 1). Supplementary figure 3 shows the spatial distributions of the confounder data. Areas with a high proportion of South Asian and black ethnicity population were concentrated in the north eastern and eastern part of the study area, respectively, which were also areas with higher deprivation and higher risks of lung cancer. Within the London area, higher levels of PM_{10} were found in the eastern part towards central London; distributions of both PM_{10} and road noise differed from that of aircraft noise (supplementary figure 3 and figure 1). Correlations between aircraft noise and potential confounders are shown in supplementary table 2 where τ=1 denotes perfect positive correlation and τ=−1 denotes perfect negative correlation. Correlations between confounders and aircraft noise were all ≤|0.30|. In the London boroughs, aircraft noise was modestly correlated with PM_{10} (τ=−0.2 for daytime noise and τ=-0.3 for night time noise) but not with road traffic noise (τ ≤0.02).

Hospital admissions

Figure 2⇓ and supplementary table 3 show the results for hospital admission for daytime and night time noise adjusted for age and sex, and with additional adjustment for ethnicity, deprivation, and the smoking proxy. For each of stroke, coronary heart disease, and cardiovascular disease the pattern was of increasing risk of admission with increasing aircraft noise, and all linear tests for trend were statistically significant (P<0.001 to P<0.05). The risk of coronary heart disease in particular, and to a lesser extent cardiovascular disease, was noticeably reduced by adjustment for multiple confounders, in particular South Asian ethnicity.

In multiple adjustment models, for daytime aircraft noise (>63 dB *v* ≤51 dB) the relative risk for stroke was 1.24 (1.08 to 1.43), for coronary heart disease was 1.21 (1.12 to 1.31), and for cardiovascular disease was 1.14 (1.08 to 1.20). Corresponding relative risks for night time noise (>55 dB *v* ≤50 dB) were 1.29 (1.14 to 1.46), 1.12 (1.04 to 1.20), and 1.09 (1.04 to 1.14). Results using the same categories for daytime as for night time noise (supplementary table 3) suggested higher relative risks for night time noise.

Mortality

Figure 3⇓ and supplementary table 4 show the results for mortality for daytime and night time noise. The relative risks of mortality were numerically similar to those for hospital admissions at the higher noise levels, although confidence intervals were wider, reflecting the smaller numbers of events. In multiple adjusted models, for daytime aircraft noise (>63 dB *v* ≤51 dB) the relative risk for stroke mortality was 1.21 (95% confidence interval 0.98 to 1.49), for coronary heart disease was 1.15 (1.02 to 1.30), and for cardiovascular disease was 1.16 (1.04 to 1.29). The corresponding relative risks for night time aircraft noise (>55 dB *v* ≤50 dB) were 1.23 (1.02 to 1.49), 1.11 (0.99 to 1.24), and 1.14 (1.03 to 1.26). Results using the same categories for daytime as for night time noise (supplementary table 4) suggested higher relative risks for night time noise. Tests for linear trend across noise categories in the fully adjusted models were significant (P<0.05) for daytime noise and coronary heart disease but not for stroke or cardiovascular disease, nor night time noise.

Sensitivity analyses

Results were materially unchanged with additional confounder adjustment for particulate air pollution and road traffic noise in the 12 London boroughs (data not shown).

Discussion

In this small area study covering a population of 3.6 million people living near Heathrow airport in London, we identified significant excess risks of stroke, coronary heart disease, and cardiovascular disease, especially among the 2% of the population affected by the highest levels of daytime and night time aircraft noise.

Strengths and weaknesses of this study

Strengths of this study include the large general population sample, inclusion of both incident events (hospital admissions) and mortality, and wide range of aircraft noise levels, providing sufficient statistical power to detect modest associations. Common to some other epidemiological studies,[11 12] we analysed aircraft noise separately from other transport noise as it is currently unclear whether noise may be additive or whether aspects of noise such as sound frequency and number and duration of noisy events may be important. Limitations include inability to adjust for confounders at individual level. We were able to adjust at small area level for ethnicity, deprivation, and a smoking proxy (and additionally for particulate air pollution and road traffic noise for a subset of 2.6 million people), but we did not have access to individual level information on confounders such as smoking; therefore results at the area level may not be applicable to individuals (ecological fallacy). Admissions for coronary heart disease and to a lesser extent for cardiovascular disease were particularly affected by adjustment for South Asian ethnicity, which itself is strongly associated with risk of coronary heart disease[28]; hence these risk estimates should be interpreted cautiously. We restricted our hospital admission analyses to the first admission within one calendar year; as we did not link across years it is possible that some may be readmissions if they occurred in different calendar years. However, point estimates at higher noise levels were similar for mortality and hospital admissions, making it less likely that this was an important source of bias.

We examined exposures to aircraft noise in 2001 and health outcomes in 2001-05. We were unable to distinguish between short and longer term effects of noise in the present study and this needs to be examined in further research. Some studies[9 12] have suggested larger effect estimates with longer duration of residence, but this may reflect exposure misclassification among more recent residents. Our data on noise exposure are left censored because of concerns about the accuracy of noise models at low levels. It is difficult to determine the resulting misclassification bias; this may also have affected the size of our risk estimates by restricting the range of noise levels across which effect sizes were estimated. A further potential source of bias is that we did not have information on migration in and out of the study areas.

Possible explanations and implications in the context of previous studies

Potential for causality of the observed associations needs to be considered in the context of previous studies, including consideration of biological plausibility and coherence. Much of the research effort concerning adverse effects of noise on cardiovascular health has focused on effects on blood pressure and risk of hypertension, hypertension being the leading cause of stroke and a major risk factor for heart disease.[29] Acute exposure to noise activates the neuroendocrine system, leading to short term increases in heart rate or blood pressure, or both[18-30] and in stress hormone levels[31]; neuroendocrine effects are also seen with chronic exposures[17] offering potential mechanisms by which environmental noise may be related to cardiovascular risk. Although these effects have mainly been studied at high exposure levels in the occupational[30 32] or experimental setting,[31] they may also occur at ambient environmental noise levels.[31] In a study conducted near four European airports (including Heathrow), noise disturbance by aircraft noise at night was associated with short term increases in blood pressure of 6-7 mm Hg.[7]

Increased risks of stroke and coronary heart disease would be expected if such physiological changes were to lead to sustained raised blood pressure.[29] A meta-analysis published in 2009[8] of five studies (totalling nearly 45 000 participants) of aircraft noise and risk of long term hypertension gave a pooled relative risk estimate of 1.13 (95% confidence interval 1.00 to 1.28) per 10 dB increase. A subsequent study of approximately 5000 adults in Sweden found long term effects on hypertension risk only in subgroup analyses, but half the study population had a family history of diabetes, which may affect generalisabilty.[5]

The previous literature concerning aircraft noise and cardiovascular disease and mortality is sparse and not fully consistent. In a cross sectional study of people living near seven European airports (including Heathrow), a significant association was observed between night time average aircraft noise and self reported heart disease and stroke (odds ratio 1.25, 95% confidence interval 1.03 to 1.51) in those who had been living in the same place for 20 or more years.[12] A census based study of 4.6 million adults aged more than 30 years in Switzerland reported an association with mortality from myocardial infarction in those exposed to the highest level of aircraft noise and who had lived at least 15 years in their place of residence; no associations were seen with stroke or cardiovascular mortality.[9] A study of adults aged 45-85 years living in Vancouver, Canada[10] did not find associations of aircraft noise with coronary heart disease mortality, neither did a population based study of about 57 000 adults aged 50-64 years in Denmark with stroke mortality.[11] These previous studies had lower population exposures to aircraft noise than in London.

As with our findings for aircraft noise, significant associations have been reported for road traffic noise and heart disease[10-35] and stroke.[11] A meta-analysis of 24 population studies of road traffic noise found a dose-response association with hypertension,[36] with a combined odds ratio of 1.03 (95% confidence interval 1.01 to 1.06) per 5 dB increase of road traffic noise, in the range 45-75 dB.

We were unable to distinguish between night time and daytime noise as they were highly correlated and so their effects could not be differentiated. More research is needed to determine if night time noise that disrupts sleep may be a mechanism underlying observed associations.[2]

Conclusions

How best to meet commercial aircraft capacity for London and other major cities is a matter of active debate, as this may provide major economic benefits. However, policy decisions need to take account of potential health related concerns, including possible effects of environmental noise on cardiovascular health. Our results suggest that high levels of aircraft noise are associated with an increased risk of stroke,

EXHIBIT 3, Page 4 of 10

coronary heart disease, and cardiovascular disease. As well as the possibility of causal associations, alternative explanations should be considered. These include the potential for incompletely controlled confounding and ecological bias, as we did not have access to individual level confounder data such as ethnicity and smoking. Further work to understand better the possible health effects of aircraft noise is needed, including studies clarifying the relative importance of night time compared with daytime noise, as this may affect policy response.

We dedicate this paper to Lars Jarup who helped initiate this project and passed away in 2010. We thank Peter Hambly, Margaret Douglass, Eric Johnson, Kayoung Lee, and David Morley for technical support and the advisory group members: Tim Williams, Yvette Bosworth (Defra), Stephen Turner (Bureau Veritas/Defra), and Nigel Jones (Extrium) who provided traffic noise data, and Darren Rhodes and Kay Jones (Civil Aviation Authority) who provided aircraft noise data.

Contributors: PE and ALH with MB, LF, SF, KdH, DF, LB, and SR conceived and designed the study. MB, LF, SF, KdH, DF, REG, LB, JG, and SB were involved in data extraction and preparation. JG, KdH, and DF were responsible for the Geographical Information System analyses. JG, KdH, and HEL interpreted the aircraft noise data. LF and MB with REG and CP carried out the statistical analyses, supervised by PE, ALH, SR, and NB. The analyses were interpreted by PE, ALH, MB, LF, NB, SR, HEL, and JG. ALH and PE drafted the initial report; all coauthors revised the report and approved the final version. MB and LF contributed equally to this paper and are joint second authors. PE is the guarantor of this paper.

Funding: The work of the UK Small Area Health Statistics Unit is funded by Public Health England as part of the MRC-PHE Centre for Environment and Health, funded also by the UK Medical Research Council. Support was received from the European Network for Noise and Health (ENNAH), EU FP7 grant No 226442. PE acknowledges support from the National Institute for Health Research (NIHR) Biomedical Research Centre at Imperial College Healthcare NHS Trust and Imperial College London. PE is an NIHR senior investigator. The funders had no role in the study design; in the collection, analysis, and interpretation of data; in the writing of the article; and in the decision to submit the article for publication. The advisory group provided advice on methodology but was not involved in the analyses, interpretation of results, or writing of the paper. The views expressed are those of the authors and not necessarily those of the NHS, NIHR, or Department of Health.

Competing interests: All authors have completed the ICMJE uniform disclosure at www.icmje.org/coi_disclosure.pdf (available on request from the corresponding author) and declare: financial support for the submitted work through the funding of the UK Small Area Health Statistics Unit by Public Health England as part of the MRC-PHE Centre for Environment and Health, funded also by the UK Medical Research Council; financial support from the European Network for Noise and Health (ENNAH), EU FP7 grant No 226442; PE acknowledges support from the National Institute for Health Research (NIHR) Biomedical Research Centre based at Imperial College Healthcare NHS Trust and Imperial College London; PE is an NIHR Senior Investigator; ALH and HEL declare consultancy fees from AECOM as part of a Defra report on health effects of environmental noise; ALH declares a Greenpeace membership but has not received any money from the organisation nor been involved in campaigns; nor other relationships or activities that could appear to have influenced the submitted work.

Ethical approval: The study was commissioned by the Department of Health in England; ethical approval was obtained from the National Research Ethics Service reference 12/LO/0566 and the Imperial College Research Ethics Committee.

Data sharing: Data are available from the data providers on application with appropriate ethics and governance permissions, but we do not hold data provider, ethics, or governance permissions to share the dataset with third parties.

EXHIBIT 3, Page 5 of 10

What is already known on this topic

Few studies have examined aircraft noise and risk of incident or fatal cardiovascular disease or stroke

Previous studies have found an increased risk of hypertension associated with aircraft noise and increased risk of hypertension, stroke, and coronary heart disease with road traffic noise

These findings are consistent with those from studies of occupational noise exposure, and experimental studies examining short term effects of noise on the cardiovascular system

What this study adds

Areas with high levels of aircraft noise related to Heathrow airport in London had increased risks of stroke, coronary heart disease, and cardiovascular disease

Interpretation should consider not only causal associations but also possible alternative explanations such as residual confounding and ecological bias

Background: Studies on the health effects of aircraft and road traffic noise exposure suggest excess risks of hypertension and myocardial infarction.

Objectives: Our aim was to assess the risk of cardiovascular disease in relation to noise from aircraft and road traffic.

Methods: This cross-sectional study measured cardiovascular disease as a diagnosis by a doctor of myocardial infarction, angina pectoris or stroke, after moving to current address, as reported by 4,861 participants living near airports in six European countries (UK, Germany, Netherlands, Sweden, Italy and Greece). Exposure was assessed using models with 1dB resolution (5dB for UK road traffic noise) and spatial resolution of 250mx250m for aircraft and 10mx10m for road traffic noise. Data were analysed using multilevel logistic regression.

Results: We found an elevated risk of cardiovascular disease in relation to average daily road traffic noise exposure after adjustment for major confounders (OR 1.19 (95% CI 1.00, 1.41)) per 10dB; participants aged 65-70 yrs were at particular risk (OR 1.34 (1.03, 1.74)). We also found an excess risk of cardiovascular disease in relation to aircraft noise at night which lost statistical significance after adjustment for confounders (OR 1.12 (0.98, 1.21)). Exposure to aircraft noise in the day was not associated with an increased risk of cardiovascular disease (OR 1.06 (0.92, 1.21)).

Conclusions: Our results suggest exposure to road traffic noise is associated with increased risk of cardiovascular disease, with a greater effect in older people. Exposure to aircraft noise at night may also be a risk factor for cardiovascular disease.

Aircraft Noise, Air Pollution, and Mortality From Myocardial Infarction

Anke Huss,[a,b] Adrian Spoerri,[a] Matthias Egger,[a] and Martin Röösli,[c,d] for the Swiss National Cohort Study Group

Objective: Myocardial infarction has been associated with both transportation noise and air pollution. We examined residential exposure to aircraft noise and mortality from myocardial infarction, taking air pollution into account.

Methods: We analyzed the Swiss National Cohort, which includes geocoded information on residence. Exposure to aircraft noise and air pollution was determined based on geospatial noise and air-pollution (PM_{10}) models and distance to major roads. We used Cox proportional hazard models, with age as the timescale. We compared the risk of death across categories of A-weighted sound pressure levels (dB(A)) and by duration of living in exposed corridors, adjusting for PM_{10} levels, distance to major roads, sex, education, and socioeconomic position of the municipality.

Results: We analyzed 4.6 million persons older than 30 years who were followed from near the end of 2000 through December 2005, including 15,532 deaths from myocardial infarction (ICD-10 codes I 21, I 22). Mortality increased with increasing level and duration of aircraft noise. The adjusted hazard ratio comparing ≥60 dB(A) with <45 dB(A) was 1.3 (95% confidence interval = 0.96–1.7) overall, and 1.5 (1.0–2.2) in persons who had lived at the same place for at least 15 years. None of the other endpoints (mortality from all causes, all circulatory disease, cerebrovascular disease, stroke, and lung cancer) was associated with aircraft noise.

Conclusion: Aircraft noise was associated with mortality from myocardial infarction, with a dose-response relationship for level and duration of exposure. The association does not appear to be explained by exposure to particulate matter air pollution, education, or socioeconomic status of the municipality.

Effects on the cardiovascular system have been reported for acute and chronic noise, occupational and residential exposure, and different types of noise—in particular, noise from aircraft and roads.[1–5] Reported health effects for chronic exposure include, for example, hypertension,[6,7] myocardial infarction,[5] cardiovascular morbidity or mortality,[2,8] and increased use of medication for cardiovascular conditions.[9]

Air pollution has also been recognized as a potential risk factor for adverse cardiovascular outcomes, including myocardial infarction.[10,11] Road traffic is an important source of both noise and air pollution, which makes it difficult to disentangle their independent associations with cardiovascular events. Indeed, measures of noise and air pollution from roads are often highly correlated.[2,12–14] Several investigators have called for studies that simultaneously examine effects of air pollution and noise,[15–17] but few such studies have been performed.[2,5,9]

The correlation with air pollution is considerably weaker for noise from aircraft than from roads, which should facilitate controlling for air pollution when examining the effects of noise. We used the data of the Swiss National Cohort[18,19] to examine the association between aircraft noise and mortality from myocardial infarction and selected other causes, taking levels of air pollution into account.

METHODS

Study Population

The Swiss National Cohort links the national census with mortality and emigration records using deterministic and probabilistic record linkage.[18] The present analysis was based on the 4 December 2000 census data and on mortality and emigration data for the period 5 December 2000 to 31 December 2005, with causes of death coded according to the 10th revision of the International Classification of Diseases, Injuries and Causes of Death (ICD-10). Enumeration in the 2000 census is near-complete; coverage was estimated at

98.6%.[20] In persons older than 30 years, 95% of deaths could be successfully linked to a 2000 census record. We excluded persons younger than age 30 years, for whom linkage is less complete.[18] We also excluded people with missing building coordinates because these coordinates were necessary to determine exposure.

The database contains information on age, sex, marital status, and education. There are also variables at the level of the municipality and residential building, describing, for example, the degree of urbanization and socioeconomic characteristics of the municipality, the age of the house and whether it had been renovated. The geocoded places of residence are also included in the census data. In general, these coordinates give a location within a few meters of the building midpoint. Data of the census of 1990 were used to identify the place of residence at that time. The censuses of 2000 and of 1990 also include information on whether persons had lived at the same place 5 years before each census, ie, in 1995 or in 1985. We were thus able to identify persons who had lived at the same place for at least 5, 10, or 15 years. The Cantonal ethics committees of Bern and Zurich approved the Swiss National Cohort.

Outcomes

Outcomes were death from acute myocardial infarction and deaths from all circulatory diseases (regardless of whether the cause of death was listed as primary or concomitant cause on the death certificate) and deaths from all causes. We also considered cancer of the trachea, bronchus or lung as an indication of smoking behavior, and stroke, which is related to hypertension. Table 1 lists the ICD-10 codes of the causes of death analyzed.

Exposure to Aircraft Noise

There are 65 civil airports and airfields in Switzerland. For the largest airport, Zurich, a dedicated noise exposure model describes yearly average exposures for the years 2001–2005 in 1 dB(A) steps and a resolution of 100 × 100 m for day (6 AM–10 PM) and night exposure for the "first hour of the night" (10 PM–11 PM), "second hour of the night" (11 PM–midnight), and the rest of the night (only the airports of Zurich, Geneva, and Basle have air traffic after 10 PM). The model from the Federal Office of Civil Aviation was used for the other 64 airports (the 2 national airports in Basle and Geneva, 11 regional airports, and 51 smaller airfields). The model includes isophones in 5 dB(A) categories. We used L_{DN}A-weighted sound pressure levels, ie, time-weighted energy based means calculated from day (6 AM–10 PM) and night (10 PM–6 AM) sound pressure levels. In this calculation, night sound pressure levels receive a 10 dB(A) penalty,[21] as previously applied by others.[2,5,9,22] We analyzed exposure in 5 dB(A) categories (<45, 45–49, 50–54, 55–59, and ≥60 dB(A)).

Exposure to Air Pollution

We analyzed individual levels of exposure to background air pollution concentration at the place of residence, using a dispersion model for PM_{10} developed by the Federal Office for the Environment for the year 2000.[23,24] The models have a resolution of 200 × 200 m. The average exposure (in $\mu g/m^3$) at the place of residence was used in the analysis. As a proxy for traffic-related air pollutants, we also considered the proximity of the place of residence to the "major road network" and the "interconnecting road network," using data from the Swiss TeleAtlas database. The major road network includes motorways, slip roads, and other roads of high importance. The "interconnecting road network" describes main roads between towns and main traffic connections within the larger cities. We used corridors of <50, 50–99, 100–199, and ≥200 m around these roads.

Statistical Analyses

We analyzed the association between aircraft noise and cardiovascular mortality using Cox proportional hazard models, with age as the underlying timescale. Time was measured from the date of birth, with delayed entry: participants entered the risk set on the 5th of December, the day after the national census. Follow-up time was censored on the earliest of emigration, death from a cause other than the outcome, or 31 December 2005. Person-years of observation were calculated as the interval between 5 December 2000 and death, emigration or 31 December 2005. We compared the risk of death across exposure categories and by the duration of living in exposed corridors (for at least 5, 10, or 15 years). Noise

TABLE 1. ICD-10 Codes, Total Number of Deaths, and Number of Deaths in People Who Lived >15 Years at the Same Residence. Swiss National Cohort Study, 5 December 2000 to 31 December 2005

Cause of Death	ICD-10 Codes	No. Deaths Included in Analysis	No. Deaths in People Who Lived >15 Years at the Same Residence
Acute myocardial infarction	I 21, I 22	15,532	8192
All circulatory disease	I 00–I 99	177,836	86,999
Cancer of the trachea, bronchus or lung	C 33, C 34	14,095	7415
Stroke	I 60–I 64 (excluding I 63.6)	25,231	12,102

ICD-10 indicates 10th revision of the International Classification of Diseases, Injuries and Causes of Death.

TABLE 2. Characteristics of Study Population (n = 4.6 million) by Aircraft Noise and Air Pollution Categories

Exposure	Total Study Population %	Women %	Age (Years) Median	Tertiary Education %	Unemployed %	Foreign Nationals %	Old Building, Not Renovated %[a]
Aircraft noise (dB(A))							
<45	91.4	52	50.7	19	2	17	26
45–49	3.5	52	50.7	20	3	21	25
50–54	2.9	52	50.2	18	3	25	30
55–59	1.9	51	49.7	20	3	26	27
≥60	0.3	49	49.1	16	4	30	30

[a]Persons living in a building older than 30 years that had never been renovated.
[b]Cut-offs correspond to median and 90th percentile.

exposure below 45 dB(A) was used as the reference category. We tested models for the proportionality assumption using statistical tests based on Schoenfeld residuals; the assumption was met for all exposure variables.

Models were adjusted for sex (model I), sex and demographic, socioeconomic and geographical variables (model II), and additionally for air-pollution levels (PM_{10}) and distance to major roads (model III). These variables included civil status (single, married, divorced, widowed), nationality (Swiss, other), educational level (primary, secondary, tertiary), setting (urban, rural), language region (German, French, Italian), type of building (older than 30 years without renovation vs. other), and socioeconomic status of the municipality (Sotomo Index[25]). Using the fully adjusted model (model III), we performed stratified analyses by age (30–72.8, 72.9–82.3, >82.3 years, corresponding to the 33.3rd and 66.6th percentiles of age at death for myocardial infarction), sex, duration of living at the place of residence (at least 5, 10, or 15 years), and whether the building was old without having undergone major renovation work (30 years or older). We tested for interaction between these variables and the effect of exposure to aircraft noise by comparing models with and without interaction terms using likelihood ratio tests. Data were analyzed in Stata (version 10, Stata Corporation, College Station, TX). Results are presented as hazard ratios (HRs) with 95% confidence intervals (CI).

RESULTS

Of 7.29 million persons recorded in the 2000 census, 2.59 million (36%) were excluded because they were younger than 30 years at the census. Another 113,855 persons (2%) were excluded because of missing building coordinates. The analyses were based on 4,580,311 people, 22,512,623 person-years, and 15,532 deaths from acute myocardial infarction. The number of deaths from the other causes is given in Table 1; 282,916 people died of any cause.

Table 2 shows the characteristics of the study population by aircraft-noise and air-pollution categories. With increasing exposure to noise, the proportion of persons with tertiary education declined, whereas the proportion unemployed, the proportion of foreign nationals, and the proportion of people living in old and unrenovated buildings increased. Similar trends were seen with decreasing distance to major roads and increasing PM_{10} values.

Table 3 gives the results from the Cox regression models for death from acute myocardial infarction and from all circulatory disease. The risk of death from myocardial infarction was higher in people exposed to aircraft noise of 60 dB(A) or more. The association became stronger when models were adjusted for sociodemographic and geographical variables and PM_{10} air pollution levels, with the strongest association being observed in the fully adjusted analysis restricted to persons who had been exposed for 15 years or longer (HR = 1.5 [95% CI = 1.0–2.2]). Figure 1 shows fully adjusted HRs of death from myocardial infarction across exposure to aircraft noise, stratified by duration of exposure at the same place of residence; the increase in the risk of death from myocardial infarction became stronger with both increasing level and increasing duration of exposure. The risk of death from myocardial infarction was also higher in those living near a major road (<100 m). This association was again strongest in the fully adjusted

Model I, adjusted for sex, using age as the underlying time scale (all models).

Model II, adjusted for sex, civil status (single, married, divorced, widowed), nationality (Swiss, other), educational level (primary, secondary, tertiary), setting (urban, rural), language region (German, French, Italian), type of building (older than 30 years without renovation versus other), and socioeconomic status of the municipality.

Model III, adjusted for the same variables as in model II and all 3 exposure variables (noise, distance, PM_{10}) in the same model.

Major roads include motorways, slip roads, and main roads between towns and main traffic connections within the larger cities.

[a]Model III, analysis restricted to persons who lived at least 15 years at the same place of residence.

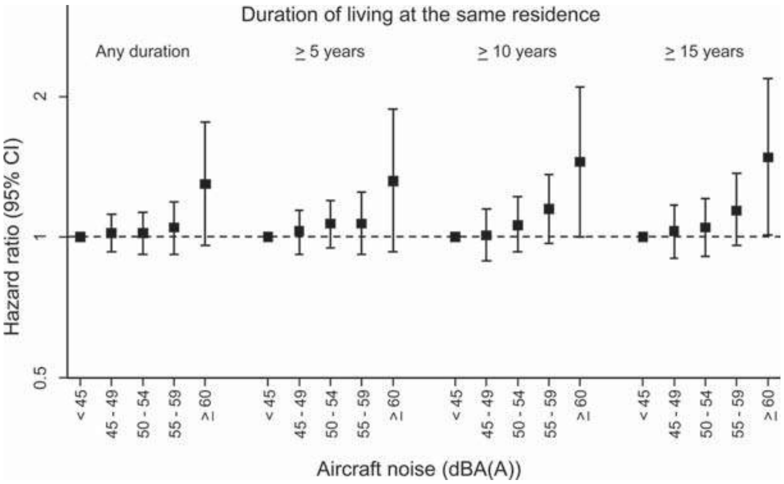

FIGURE 1. Mortality from myocardial infarction and estimated exposure to aircraft noise, Switzerland, 2000–2005. Results from model III are shown for persons who at the time of census had lived in the same place of residence for any duration, or for at least 5, 10, or 15 years.

model, restricted to people who had been exposed for at least 15 years (Table 3). No association was seen with increasing concentrations of PM_{10}.

The risk of death from all circulatory disease was not associated with aircraft noise or levels of PM_{10}, although it was slightly increased near major roads (Table 3). Similarly, mortality from cancer of the trachea, bronchus, or lung was not increased in those exposed to high levels of aircraft noise, but it was increased among people living close to a major road and among people exposed to high levels of PM_{10}. The association with distance to major roads was attenuated when adjusted for sociodemographic and geographical variables. No associations were observed with the risk of death from stroke (Table 3). Finally, there was little evidence for an association with mortality from all causes, in either sex-adjusted or fully adjusted analyses. The HR comparing ≥60 dB(A) with <45 dB(A) for death from all causes from the fully adjusted analysis (model III) was 1.0 (95% CI = 0.96–1.1).

Results were similar in sensitivity analyses when considering day-time or night-time exposures rather than time-weighted energy-based means (data not shown). Fully adjusted HRs from model III comparing highest (≥60 dB(A)) with lowest (<45 dB(A)) levels of exposure to aircraft noise tended to increase with increasing age, and were higher in men compared with women. Noise exposure was also higher for people living in old buildings that had not been renovated compared with new or renovated buildings (Fig. 2). Formal tests of interaction, however, failed to reach conventional levels of statistical significance ($P > 0.32$).

Additional information is provided in 2 supplementary online tables. eTable 1 (http://links.lww.com/EDE/A426) shows the distribution of person-years and deaths in each exposure category. eTable 2 (http://links.lww.com/EDE/A426) gives Pearson correlation coefficients showing that daytime exposure ($L_{Aeq,\ day}$) was correlated with $L_{Aeq,\ night}$ and with L_{DN} exposure. Correlation between aircraft noise and distance to roads or PM_{10} levels was weak, with Spearman rank correlation coefficients ranging from 0.01 to 0.22.

DISCUSSION
